FOREWORD

The year 1951 was one of generally accelerating activity in the minerals industries in the United States, notably in those concerned with strategic commodities. This growth was engendered by the rapidly expanding materiel needs of the free world in prosecuting its drive against aggression, particularly in Korea. This MINERALS YEARBOOK, the latest in an extended series of annual volumes, records the accomplishments of the minerals industries in that year. As such, I hope that the volume will serve well those in industry, in Government, and among the general public who have need for basic economic data on minerals. Such changes as have been made in this volume over previous editions were in line with the Bureau of Mines' continuing efforts to enhance the usability of its data through improvement of its methods of collection, processing, and presentation of data.

J. J. FORBES, *Director*.

PREFACE

The present format and content of the MINERALS YEARBOOK have developed over the years because of the ideas and efforts of many individuals, in industry, private organizations, and Government agencies—both State and Federal. Drawing upon these contributors, its preparation each year has involved continued efforts by the Bureau of Mines to improve both the quality and manner of presentation of the information incorporated into the volume. As a practicable matter, it has not always been possible to incorporate all appropriate suggestions outstanding into any volume. Further, some suggestions, while meritorious in themselves, could not be adopted because they were not in accordance with the general tenor of the Yearbook. Nevertheless, the Bureau of Mines hopes and urges that all users of the MINERALS YEARBOOK continue to send to the Bureau for consideration any and all suggestions they may have regarding improvement of these annual volumes.

Questionnaires answered by mineral producers and users are the source of most of the information herein. Other sources are the business press, trade associations, scientific journals, international organizations, and Government agencies. In particular, data on foreign trade are obtained from the United States Department of Commerce, and data on foreign production and developments largely through the United States Foreign Service.

The reader is reminded that the purpose of the MINERALS YEARBOOK is to provide a convenient and reasonably comprehensive reference summary for United States mineral activity in the subject year. It is not the source of prompt statistics from canvasses conducted by the Bureau of Mines. The first publication of Bureau statistics is generally a release issued before the individual chapter preprints. Such releases are available from the Publications Distribution Section, U. S. Bureau of Mines, 4800 Forbes Street, Pittsburgh 13, Pa. The individual MINERALS YEARBOOK chapter preprints, which are issued months before the entire volume, are sold for nominal amounts through the offices of the Superintendent of Documents. Bibliographic lists of such current releases are available in the monthly and annual supplements to the List of New Publications, Bureau of Mines, and in the Monthly Catalog of U. S. Government Publications, sold by the Superintendent of Documents, Government Printing Office.

Cooperating with the Bureau of Mines in the conduct of statistical canvasses in their respective States were the following State officials to whom grateful acknowledgment is made:

Alabama: Walter B. Jones, State geologist, Geological Survey of Alabama, University.
Alaska: Leo Saarela, commissioner of mines, Department of Mines, Juneau.
California: Olaf P. Jenkins, chief, Division of Mines, and State mineralogist, Department of Natural Resources, San Francisco.

Digitized by Google

Florida: Herman Gunter, director, Florida Geological Survey, Tallahassee.
Georgia: Garland Peyton, director, Department of Mines, Mining and Geology, Atlanta.
Illinois: M. M. Leighton, chief, Illinois State Geological Survey Division, Urbana.
Iowa: H. Garland Hershey, district and State geologist, Iowa Geological Survey, Iowa City.
Kansas: John C. Frye, executive director, and R. C. Moore, State geologist and director of research, State Geological Survey of Kansas, Lawrence.
Kentucky: Arthur C. McFarlan, director, and Daniel J. Jones, State geologist, Kentucky Geological Survey, University of Kentucky, Lexington.
Maryland: Joseph T. Singewald, Jr., director, Department of Geology, Mines and Water Resources, Baltimore.
Michigan: Frank Pardee, State geologist and division chief, Geological Survey Division, Department of Conservation, Lansing.
Missouri: Edward L. Clark, director and State geologist, Department of Business and Administration, Division of Geological Survey and Water Resources, Rolla.
New Hampshire: T. R. Meyers, State geologist, Mineral Resources Committee, New Hampshire State Planning and Development Commission, Durham.
New Jersey: Meredith E. Johnson, State geologist, Bureau of Geology and Topography, Department of Conservation and Economic Development, Trenton.
New York: John G. Broughton, State geologist, New York State Science Service, Office of Geology, Albany.
North Carolina: Jasper L. Stuckey, State geologist, Department of Conservation and Development, Division of Mineral Resources, Raleigh.
Oklahoma: Robert H. Dott, director, Oklahoma Geological Survey, Norman.
South Dakota: E. P. Rothrock, State geologist, South Dakota State Geological Survey, Vermillion.
Texas: John T. Lonsdale, director, Bureau of Economic Geology, University of Texas, Austin.
Utah: Arthur L. Crawford, director, Utah Geological and Mineralogical Survey, University of Utah, Salt Lake City.
Virginia: William M. McGill, State geologist, Department of Conservation and Development, Geological Survey Division, Charlottesville.
Washington: Sheldon L. Glover, supervisor, Division of Mines and Geology, Olympia.
West Virginia: Paul H. Price, State geologist, West Virginia Geological and Economic Survey, Morgantown.
Wisconsin: E. F. Bean, State geologist, Wisconsin Geological and Natural History Survey, University of Wisconsin, Madison.

Advance planning for this edition was done by my predecessor, Leonard L. Fischman, who before his resignation from the Bureau in February 1953 edited a number of the chapters. His immediate assistant and mine was Robert E. Herman, who supervised the Yearbook staff in processing of manuscripts and who during the last year undertook some of the editorial functions. Yearbook staff members included Blanche G. Robertson, Ethel M. Tucker, Thelma K. Stewart, Robert V. Crosson, Janet B. Riddle, and Joseph G. Dubuque. In addition, special credit for staff work on this Yearbook should go to Sally S. Nishiyama, for her helpfulness in keeping the work in order and progressing. The manuscript was edited for style improvement, punctuation, and type specification by Mabel E. Winslow, Estelle R. Templeton, Hazel J. Stratton, and Betty Ruth Cattell of the Office of Mineral Reports. Shortly after the first of the manuscripts for this edition were submitted by the authors, Adelaide B. Palmer, who for a number of years had served in a highly commendable fashion as draftsman for the Yearbook as well as for other releases of the Bureau's Washington office, was forced by serious illness to go on extended leave and subsequently to retire. Her duties, which included not only

Digitized by Google

drafting many of the Yearbook charts but also seeing that the many additional charts prepared at the Bureau's Pittsburgh office under the supervision of Louis F. Perry (later Gene Nicolai) were completed in good order, were subsequently undertaken by Caroline G. Holcomb (on a temporary appointment) and then by Orrie E. Vigal.

All but two of the world production tables in this volume were prepared under the direct supervision of Mrs. Berenice B. Mitchell, of the Foreign Minerals Region. Among other Bureau of Mines statisticians and researchers who rendered substantial assistance to the authors of this volume were: In Washington, D. C.—Hope R. Anderson, Kathleen Joyce D'Amico, Elizabeth K. Elsner, Nina L. Jones, Naomi W. Kearney, James G. Kirby, Ann C. Mahoney, Elizabeth A. Miller, Zena M. Mohme, Robert C. Morris, Elizabeth J. Reid, Dora D. Springer, Mary E. Trought, and Virginia E. Wrenn. In Juneau, Alaska—Opal Y. Sharman. In Denver, Colo.—Stella K. Drake. In Minneapolis, Minn.—Eunice M. Clark, William V. Jokela, Luella Niemeyer, and Matthew G. Sikich. In Albany, Oreg.—Catherine M. Moll. In Pittsburgh, Pa.—Roy H. Davis. In Salt Lake City, Utah—Virginia C. Halverson.

PART I. GENERAL REVIEWS

Review of the Mineral Industries in 1951

By Paul W. McGann

GENERAL SUMMARY

THE MINERAL INDUSTRIES of the United States enjoyed a record year in 1951 as a result of the high level of employment and demand sustained by the Korean War and by the general progress of the economy. The aggregate value of mineral production increased over 1950 and was above the previous high. There was but little growth, however, in physical output of minerals during the year above the high level at which the year began. Nevertheless, physical production was 11 percent above the previous year and 6 percent above 1948, the previous peak year.

Consumption and imports of minerals for the year were also the highest in history. Petroleum consumption and imports reached new highs. Bituminous consumption increased 3 percent, but anthracite consumption continued to decrease. Minerals-manufacturing orders, sales, and inventories reached the highest values ever.

PRODUCTION

Value of Production.—The historic peak value of mineral-industry production was reached in 1951 for all major categories. The mine value of fuels produced was 13 percent higher than in 1950; other nonmetallic minerals 14 percent higher; and metals 24 percent. This gave a 14-percent increase for all minerals, 10 percent above 1948, the previous high.

The value of mineral production for 1947–51 is summarized in table 1. Detailed data may be found in the Statistical Summary chapter of this volume.

TABLE 1.—Value of mineral production in continental United States, 1947–51, by mineral group

[Millions of dollars]

Year	Nonmetallic			Metallic	Grand total
	Fuels	Other	Total		
1947	7,181	1,345	8,526	1,084	**9,610**
1948	9,495	1,559	11,054	1,219	**12,273**
1949	7,912	1,567	9,479	1,101	**10,580**
1950	8,681	1,823	10,504	1,351	**11,855**
1951	9,770	2,084	11,854	1,670	**13,524**

Digitized by Google

Volume of Production.—The high monthly production of minerals in 1951 continued at the rates set in the fall of 1950 and previously reached in 1948. The unique feature of 1951 was that these high rates were sustained throughout the entire year. There was not a significant rate of change during this "plateau" period, but a perceptible monthly increase of about ½ percent might be detected in the Federal Reserve adjusted index of mineral production. The only significant dip of adjusted monthly mineral production (5 percent) during the year was the result of the 21 percent July decline in bituminous-coal production, but recovery followed immediately in August. The most violent fluctuation in monthly production was suffered, as usual, by the anthracite industry, which had a 46-percent decrease in March. Other mineral industries enjoyed unusual stability, led by crude-petroleum and pig-iron production. Metallic mining (other than gold and silver) experienced only one unseasonable low period, about 9 percent lower in July and August, owing to declines in copper and zinc output. Smelting and refining of nonferrous metals also was lower by about 6 percent in terms of monthly output in August and September as a result of the short strike of the International Union of Mine, Mill, and Smelter Workers in these months. Gold and silver production declined throughout the year.

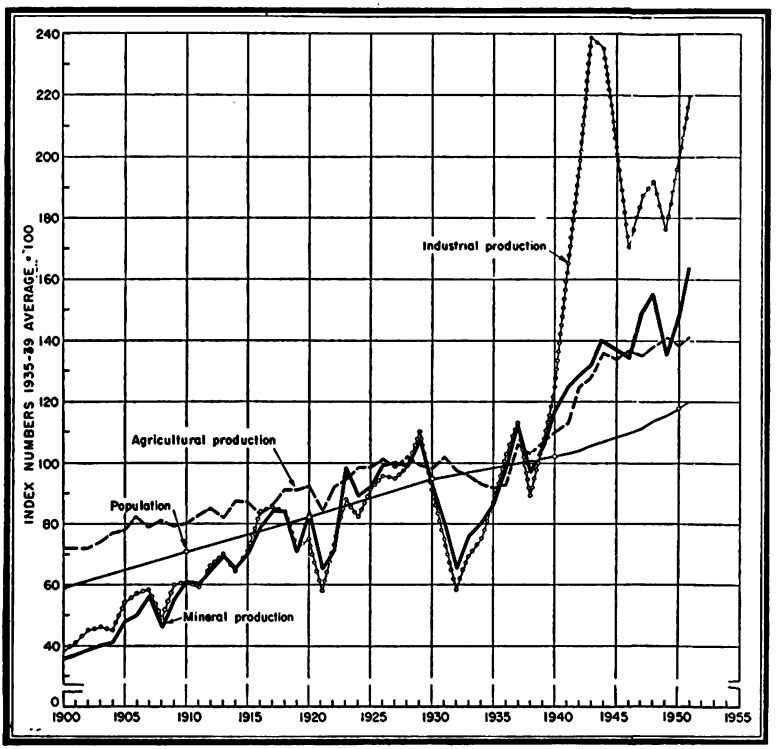

FIGURE 1.—Physical volume of mineral production compared with industrial production (manufactures and minerals), agricultural production, and population, 1900–51. Sources: Federal Reserve Board, U. S. Department of Agriculture, and Bureau of the Census.

Digitized by Google

The output of nonmetallic minerals increased throughout the year at about 1 percent per month. Cement, however, declined every month from March to October but recovered thereafter. Other nonmetallics, for which monthly or quarterly data are collected by the Bureau of Mines, however, increased steadily (gypsum, sulfur, lime, soda ash, glauber's salt, salt cake, and fluorspar).

The increase for all nonmetallic output over 1950 was 9 percent; for metals, 5 percent; bituminous coal, 3 percent; and crude petroleum, 14 percent. The decrease for anthracite was 3 percent.

Number, Size, and Age of Firms.—The gross number of mining firms remained constant at 34,100, although for the first two quarters it reached 34,200. This was the result of approximately 3,700 new businesses balancing 3,700 discontinued firms. These were the lowest turnover figures in the postwar era. There were 1,800 transfers of ownership of going concerns during the year, the lowest number since 1944.[1]

The number of active proprietors in mining industries also remained the same, 46,000, from 1950 to 1951, and was approximately constant within each major category: Metal, 9,000; nonmetallic, 7,000; anthracite, 2,000; bituminous, 6,000; and crude petroleum, 22,000. (These figures are greater than the number of firms, of course, because of partnerships.) Active proprietors are unimportant in mineral manufacturing.

The Bureau of the Census' annual survey of manufactures for 1951 in general shows minor changes in establishment size distributions of major mineral-manufacturing industries between 1950 and 1951 (*see* table 2).

Of the firms started in 1950, 63.6 percent lasted one year or more into 1951, and 47.6 percent of those started in 1949 lasted until 1951. These figures are about the same as for manufacturing and for all industries. A modified "life-expectancy table" for mining and quarrying firms is also about the same as for manufacturing and as for the average of all industries. (For example, the percentage of mining firms remaining in operation one additional year if 5.5 years of age is 88.4 percent.) The median age of mining firms is 5.1 years, higher than that of any other major industrial group except financial, insurance, and real estate, and is the highest since the data have been collected beginning in 1945. Mining and quarrying firms appear to gain life expectancy above the average business as they grow older. The cumulative age distribution curve begins at an average industry value at 0.5 year (84.4 percent being older), ranks fifth out of 8 major industrial groups at 2.5 years, and third at 4.5 years (behind wholesale and financial, insurance, and real estate). It gets closest to the leader (financial, etc.) and becomes second at 7.5 years, the last value tabulated, than it is at any value after 0.5 year. At that age, 42.8 percent survive (the next highest industrial group only has 36.9 percent survival).[2] This life-expectancy data seem to indicate that if mining "differs" from other industry because of exhaustibility of deposits, other factors seem to work more for reducing the life of firms in other lines of endeavor.

[1] Source: U. S. Department of Commerce, Bureau of the Census, Annual Survey of Manufactures, 1951: Washington, 1953, pp. 146–161.
[2] These are Standard Industrial Classification numbers.
[3] Figures for the size category 1–249 were withheld by the Bureau of the Census, because the estimates did not meet its publication standards, either on the basis of associated standard error of estimate or on the basis of consistency review.

CONSUMPTION AND STOCKS

Annual apparent consumption of most minerals increased over the previous year in 1951. Major exceptions were anthracite, copper, lead, zinc, chromite, molybdenum, tungsten, tin, cadmium, and sulfur. These exceptions were largely explained by increases of stocks of chromite, and sulfur, but decreased net imports was the cause for decreases in tungsten and lead. Anthracite consumption declined moderately.

Significant changes in stocks took place during 1951 only for manganese, cadmium, tungsten, tin, mercury, and platinum-group metals. All were net withdrawals except for cadmium and platinum-group metals.

There was no decrease in dependence upon imports for strategic minerals for which domestic supplies are inadequate or uneconomic. The decreases in net imports that took place resulted instead from temporary decreases in foreign supplies. The decline in mercury imports was largely responsible for the unusual increase in price (the 1951 annual average price was over two and one-half times that of 1950).

Orders, Sales, and Inventories.—Mineral-manufacturing industries enjoyed the highest sales, inventories, and orders in their history. New orders in the primary-metals industries and the annual accumulation of unfilled orders for 1951 were 16 and 26 percent, respectively, above the previous highs of 1950.[3]

Peak backlogs of unfilled orders accumulated in 1951. The year-end backlog was about 3.8 months' worth, about a 10-percent increase over that at the end of 1950. Although these backlog lengths were smaller than for most other durable-goods industries, they were well above those of nondurables. The monthly peak for new orders of primary-metals industries (adjusted for seasonal variation) was in October, but the second half of the year was about 12 percent below the first half. The monthly peak was in January for other durables and also for all nondurable-goods industries, and new orders for the former at the year end were being received at about a 30-percent lower rate, whereas new orders rate for nondurables declined only about one-half as much percentagewise. Unfilled orders were 27 percent higher at the year end for primary metals and 73 percent for all durables but fell 48 percent by December for nondurables from the March peak. Unfilled orders for primary metals were down 5 percent from their October peak, but December was the high for all durables.

Sales (seasonally adjusted) were at a peak in May for primary metals as was true for all manufacturing, all durable- and nondurable-manufacturing industries. Petroleum and coal products had adjusted sales peaks in October–November, when there was a secondary peak for primary metals and the other manufacturing groups.

Inventories (seasonally adjusted) were the highest on record and climbed almost every month of the year, finishing about one-sixth greater at year-end than at the beginning for both primary-metals and petroleum- and coal-products firms. This approximately equaled the increase for nondurable-manufacturing firms (17 percent) but was only half the increase in the durable-goods group of firms (36 percent).

Behavior of inventories of mineral-manufacturing establishments was very little different from those of firms discussed above. For petroleum- and coal-products establishments 1951 year-end inventories were 12 percent above 1950, and for primary metals, 14 percent. For all manufacturing establishments industry categories, the increase in inventories (25 percent) was slightly less than for firms. For all durable-goods industries establishments the increase was 39 percent.[4]

As might be expected, detailed industrial classifications of mineral-manufacturing establishments showed notably different changes in inventories between 1950 and 1951. Byproduct-coke-oven inventories declined 6 percent because of a 9-percent decrease in raw materials and goods in process inventories. Other decreases were primary copper, 18 percent; primary minor nonferrous metals, 7 percent; and secondary nonferrous metals, 3 percent. The decreases in primary copper and secondary nonferrous inventories were due to large declines in finished-goods inventories resulting from acute shortages in these areas; but the shortages also caused primary copper to suffer a substantial decline in raw materials and goods in process inventories.

INCOME AND INVESTMENTS

National Income Originated.—The increase for the mineral industries in national income originated during 1951 was greater than ever before,[5] exceeding that for 1948, the previous high. The percentage increase in business income before taxes was higher than the increase in wages and salaries and supplements thereto, except for anthracite and bituminous coal, where the business income declined from 1950.

The national income originated in mineral industries is potentially perhaps the best measure of their normal economic importance (although it might not be a good measure of their strategic nature). Unfortunately, national income originated is a curious hybrid estimate for the mining industries as such, consisting of labor income for mining establishments but business income only for firms classified as mostly mining. The disparity between firms and establishments in industrial classifications is greatest as regards mining industries because major establishments are owned by large, integrated firms ordinarily classified as manufacturing. The business income of these firms that derives from mining is almost never publicly segregated. (Thus it might be better to regard these national income data as integrated minerals-industry data if the manufacturing industries were classified in a way that clearly allowed this.) Anthracite mining is an exception, in that virtually all of its establishments are controlled by anthracite-mining firms.

Corrections of mining business income to allow for business income counted in manufacturing appear to be most necessary in the case of crude-petroleum production, nonmetallic minerals and bituminous coal—in that order. Despite sizable production of metallic ores by subsidiaries, the Department of Commerce business-income estimate does not seem to need correction for metal mining (or for anthracite). The corrections for 1951 are given in table 5. The corrections were made by using data from the Census of Mining Industries in 1939 in addition to the Commerce Department data of that and subsequent years. (These were checked against Bureau of Internal Revenue data where available.) The Census data essentially provide a value-added figure for all establishments in each industry from which business income for all establishments may be roughly estimated by subtracting wages and salaries (including supplements thereto) (from 1939 Census), estimated depreciation, and estimated business taxes (from Bureau of Internal Revenue and Commerce Department data). For purposes of this illustrative correction, other less important adjustments have been ignored because it is not pretended that the adjustments calculated are accurate enough to warrant further refinement.

Another interesting national income estimation is that which attempts to measure the amount of income originating in transportation and manufacturing industries devoted to production and distribution of refined mineral products. (In this comparison the correction of mining income will be ignored because the integrated manufacturing firms to which the correction would apply will be included in the total anyway.) Table 6 shows the national income

The adjustments for manufacturing are the fraction that the 1951 value added of mineral industries is of the whole manufacturing category of which they are a part, according to the Annual Survey of Manufactures.[6] The railroad adjustment is the 1951 sum of gross freight revenue from products of mines and minerals in manufacturing categories as a fraction of total gross freight revenue. A tonnage ratio was used for water transport, because of the almost complete lack of comparable economic data for water transport. The highway adjustment was a partly educated guess.

Business Income and Dividends.[7]—Mining corporations constituted the only major industrial group whose income after taxes rose from 1950 to 1951 (9 percent). Wartime corporate income-tax increases and price controls led to declines in annual corporate income after taxes in bituminous coal (4 percent), nonmetallic mineral mining (1 percent), the primary manufacturing of iron and steel (9 percent), and nonferrous metals (4 percent). None of these declines were as great percentagewise, however, as those for all industries (12 percent) or for all manufacturing (14 percent). These were overbalanced, on the other hand, by unusually large percentage increases in annual corporate income after taxes for metal mining (15 percent), crude petroleum production (12 percent), and petroleum refining and coal products (19 percent).

Large percentage increases in annual income before taxes were not enough to enable iron and steel (24 percent) and nonferrous metals (24 percent) to retain an increase after taxes. In crude-petroleum the percentage increase after taxes was substantial (12 percent) even though the increase before taxes was more modest (17 percent). This was largely due to the effects of percentage depletion allowances on crude petroleum.

All mining industries increased their 1951 dividends except anthracite. This was true also of the total of all industries, but manufacturing dividends generally were curtailed. Dividends of petroleum and coal products and nonferrous products were increased (21 and 12 percent, respectively), although iron and steel decreased slightly (2 percent).

Quarterly cash dividends publicly reported [8] rose throughout 1951 for mining firms as they did for all industry and for manufacturing firms. As usual, the seasonally high fourth quarter dividends for mining were about 50 percent above those in other quarters.[9]

Undistributed corporate income for mining firms in 1951 increased slightly, although it fell sharply for all manufacturing and all industries. Modest declines in undistributed income were observed for bituminous and nonmetallic mining and for iron and steel and nonferrous-products industries.

Quarterly corporate profits behaved differently for the major mineral-manufacturing industries, but dividends rose and current assets and liabilities increased for all.[10] Profits before taxes as a percentage of sales were well above the average of all manufacturing for petroleum refining and nonferrous metals and were somewhat below for other products of petroleum and coal. Profits after taxes as a percentage of stockholders' equity were also well above the manufacturing average for the first two and about equal to it for the latter group. For all manufacturing groups, profits fell during the year because of the effects of rising costs and price controls, which caused operating profits to decline, and because of 1951 corporate income taxes.

Investment.—Expenditures on new plant and equipment in 1951 by mining firms were 31 percent higher than in 1950. This increase

[7] Annual data discussed in this section are from Survey of Current Business, vol. 32, No. 7, July 1952, pp. 16–21.
[8] Work cited in footnote 3.
[9] Although some dividends are paid each month, the dividends from the last month in each quarter for mining firms is always about 10 times greater than the sum of the other two months. This discrepancy is much less for other industrial categories.

was in keeping with that of all industry (24 percent) but less than for all manufacturing firms (45 percent). Mineral manufacturing showed especially great increases with nonferrous (131 percent) and iron and steel (100 percent). Petroleum and coal products were closer to all mining (32 percent). These investments were stimulated considerably by the accelerated tax-amortization allowances provided for war industries under the Defense Production Act.

Quarterly expenditures on plant and equipment by mining firms (adjusted for seasonality) showed a plateau over the second, third, and fourth quarters at an annual rate of $960 million (3 percent above the actual amount for the year). The unadjusted peak took place in the fourth quarter as did the adjusted peak for all industry. Quarterly expenditures of mineral-manufacturing industries on plant and equipment reached peaks (unadjusted for seasonality) in the fourth quarter 30 to 50 percent above the fourth quarter of 1950.[11]

The annual increases in expenditures on new plant and equipment for mineral-manufacturing establishments followed closely that for firms, as was true of all manufacturing industries. The increase for petroleum and coal products was 35 percent and for primary metals 105 percent. In primary metals, as for all manufacturing, the percentage increases in expenditures on new structures and additions to plant were twice as large as for new machinery and equipment, 161 and 87 percent, respectively. For petroleum and coal products the opposite was true (14 and 69 percent, respectively) because most of the investment was made as additions to old "establishments in operation" rather than new "establishments under construction." For petroleum and coal products only 0.1 percent of the investment was in new establishments, whereas for primary metals 16 percent was a much higher ratio than for any other major manufacturing category. The figure for all manufacturing was 7 percent, which was typical for other major manufacturing industries.

Certain more detailed mineral-manufacturing classifications showed quite large increases in these expenditures. For example, fertilizer-industries plant and equipment expenditures increased 111 percent over 1950; blast furnaces and steel mills, 113 percent; and primary nonferrous, 176 percent. A related industry of much interest to mining, the construction and mining machinery industry, increased its investment expenditure 207 percent over 1950.[12]

The above difference in fixed investment patterns between mineral manufacturing industries was largely due to the differing impacts of construction schedules covered by certificates of necessity for accelerated tax amortization of emergency facilities. For steel and related programs, about two-thirds of the fixed-asset investment in the fourth quarter of 1951 was under certificates of necessity; for nonferrous metals, seven-eighths; but for petroleum refining, only one-twentieth.[13]

The calculation of investment by firms generally leads to underestimation of investment of miming, transportation, and other facilities and overestimation of what are apparently manufacturing facilities because all the investment of integrated firms is generally

[11] Survey of Current Business, vol. 33, No. 4, April 1953, p. 9.

[13] Defense Production Administration data on "value put in place" compared with data on expenditures for new plant and equipment.

Digitized by Google

counted as that of manufacturing firms. In the case of oil companies only 11 percent of the industry's $2,948 million domestic investment was in manufacturing (that is, refining and chemical plants), whereas 65 percent was in production of crude petroleum, 13 percent in transportation, and the remainder in other nonmanufacturing facilities.[14]

Expenditures on plant and equipment are by no means all of gross investment. In petroleum, working capital in the 30 largest companies increased $492 million through 1951.[15] For firms manufacturing coke and other products of petroleum and coal (but not for refining firms) the 1951 working capital increment of $30 million was 1.4 times greater than the net increase of other assets, and the increase in current assets of $56 million was 1.3 times the gross increase in fixed assets plus changes in other assets. The primary nonferrous firms show a different pattern of asset growth, dominated by fixed assets in 1951. The net increase in noncurrent assets was $371 million, 5.7 times the increase in net working capital, and the gross increase was $486 million, 1.3 times the increase in current assets.[16]

It is interesting to compare net and gross fixed investment in 1951. Depreciation and depletion as a percentage of the sum of depreciation and depletion plus the net increase in fixed assets during 1951 was 53 percent for petroleum-refining firms, 45 percent for coke and other petroleum and coal manufacturing, and 31 percent for primary nonferrous metals. For all manufacturing, the percentage was 42.

Tax Yields.—Federal corporate tax liability of mining firms rose 29 percent over 1950. This increase was slightly less than that of all industry (32 percent) and well below all manufacturing (40 percent).

Tax liabilities for mineral industries as a percentage of corporate income before taxes were much less than for other industries. For example, tax liability for all industries was 56 percent of the income before taxes; all manufacturing was 59 percent; iron and steel products, 61; nonferrous-metals-manufacturing firms, 58; and pipeline transportation, 58. On the other hand, crude petroleum was only 31 percent; metallic mining, 38; and nonmetallic mining, 44. The differences were no doubt largely due to the differing effects of percentage depletion allowances (and to a lesser extent, the effects of intangible drilling and development costs). Petroleum-refining firms, being largely integrated to include crude output, brought the percentage of manufacturing firms producing products of petroleum and coal down to 34 percent.[17]

The effects of percentage depletion on wholesale gasoline prices were counteracted by the Federal and State excise taxes, which produced more revenue than was applied for highway purposes. The Federal excise rose ½ cent per gallon to 2 cents during 1951. (The Federal gasoline excise should probably be included with other Federal excises on motor vehicles, parts, and tires when compared with Federal highway expenditures and with revenue-producing taxes on other modes of transportation such as railroads.) Federal gasoline

Digitized by Google

excises produced about $570 million, and $455 million was spent on highways, leaving net revenue produced of about $115 million. About $270 million in State taxes in 1951 [18] was diverted to non-highway uses. These net revenue contributions of $385 million gasoline taxes approximately cancel the reduction in income tax borne by gasoline (estimated on a refinery value basis as a share of crude-oil final product). Thus, it might be said that the net effect of the tax systems is to provide encouragement through percentage depletion primarily to other oil products than gasoline, mainly diesel and distillate fuel oils, and residual fuel oil, and to natural gas (Federal lubricating-oil excises also approximately balanced estimated tax-relief effects of percentage depletion on these products in 1951). The stimulating effects of percentage depletion upon crude-petroleum production no doubt contributes somewhat to increased supplies of gasoline and lubricants, however, despite the depressing effects of net revenue-producing excises, because there has been a slight increase recently in the refinery yields of gasoline and lubricating oils in response to increased demands. Other qualifications to these propositions should be examined if the data are to be improved, for example, the extent to which highway expenditures can be considered net capital expenditures instead of current operating replacement. Another point to be studied is the behavior of the average for the industry of marginal effective income-tax rates for individual firms, especially during years of excess profits taxes, such as 1951.

LABOR

Wages.[19]—Wages and salaries received in mining industry firms were 13 percent above 1950; in petroleum- and coal-products industry, 13 percent; nonferrous metals and their products, 17 percent; and iron and steel, 24 percent. The increases inside the mining industries were equally uneven, ranging from 2 percent for anthracite to 21 percent for metal mining. Bituminous wage and salary payments increased 10 percent, and those of crude petroleum and nonmetallic minerals both rose 17 percent.

Percentage increases in supplements to wages and salaries were about one-fourth less than those of wages for each of the above minerals industries except crude-petroleum and nonferrous-metals firms, whose supplements each increased 20 percent over 1950.

In general, labor income increases were slightly less in minerals industries than for the rest of the economy. Salaries and wages for all industries increased 17 percent and supplements thereto 15 percent and for all manufacturing 18 and 16 percent, respectively.

Employment.—Annual average employment increased in all mining from 904,000 to 920,000, decrease in anthracite (8 percent) being overbalanced by increases in bituminous, metallic-mining firms, nonmetallic, and crude petroleum (1, 4, 8, and 3 percent). There has been an irregular downward trend in mining employment since World War I. Mineral-manufacturing employment had a significant net increase in 1951 as a result of increases in all major categories—7 percent in

[18] Duff, Dahl M., Gasoline Taxes: Oil and Gas Jour., vol. 51, No. 35, Jan. 5, 1953, pp. 33-34.
[19] Work cited in footnote 5, p. 18.

Digitized by Google

petroleum and coal products, 6 percent in blast furnaces and steel works, and 3 percent in primary nonferrous metals.

The increase in the annual average hid a decline throughout the year from 932,000 in January to 916,000 in December (July, the vacation month, was as low as 906,000). The high metals-mining annual employment was the result of a high plateau of monthly employment, but there were increases throughout the year for nonmetallic mining and crude petroleum, December being greater than January by 7 percent for both. Coal employment fell throughout the first half of the year to a stable low level the last half. Monthly patterns of production-worker employment were the same as for all employees. Mineral-manufacturing employment (both of all employees and of production workers) increased throughout the year with coke, petroleum refining, and blast furnaces and steel works gaining from January to December but primary nonferrous metals declined slightly.[20]

Unemployment in mining industries was 3.3 percent in 1951, nearly half that of 1950 and the lowest since the statistic has been estimated, beginning in 1946. In the fourth quarter a low of 1.5 percent was reached. The annual figure was slightly above that for all workers and equal to manufacturing. The fourth-quarter percentage was lower than that of any industrial group.[21]

Hours.[22]—The 1951 annual average of weekly hours worked increased over 1950 for all mining industries except anthracite mining. Bituminous and petroleum increases were small, but nonfuel mining increases were an hour or more. The highest annual average was 46 hours for copper mining, and the lowest 30 hours for anthracite. All other mining industries were between 39 to 43 hours, except bituminous at 35 hours and nonmetallic mining 45 hours.

The largest increase of average weekly hours during the year took place in iron mining, whose December average was 2.1 hours more than in January. Other minerals industries had increases of less than an hour over the year.

Average Earnings.—In 1951, there were significant increases in average annual earnings per full-time equivalent employee. The average for all mining rose 13 percent, which was better than in mineral manufacturing concerns because in both petroleum and coal products and in nonferrous metals the increase was only 8 percent; iron and steel's average rose 11 percent. The leader in mining was bituminous coal with 17 percent, followed by metal mining at 15 percent, both anthracite and nonmetallics with 10 percent, and crude petroleum at 8 percent. The average annual earnings for all industries and for all manufacturing increased only 8 and 9 percent, respectively.

The level of average annual earnings in mining was 20 percent above all industries and 8 percent above all manufacturing. In fact, the only major industry group above mining industries was transporta-

Digitized by Google

tion, 3 percent above mining. The highest mineral industry was petroleum and coal manufactured products at $4,650 per year. All the other mineral categories were grouped between $3,841 and $4,162 annually, except anthracite and nonmetallics, with $3,435 and $3,596, respectively—both still well above all industry at $3,253. This no doubt depends in part upon the high degree of unionization of mineral industries and high proportion of skilled workers required.[23]

Average weekly earnings increased throughout the year for every mineral industry except anthracite, although somewhat irregularly for some industries because of variations in average weekly hours worked and sudden jumps in average hourly earnings as a result of industry-wide changes in union contracts.[24]

Average hourly earnings also increased during 1951 for all mineral industries. Copper mining had the smallest increase in average hourly earnings for the year, 6 percent, and iron ore the highest, 13 percent. The others all had 10- or 11-percent increases except crude petroleum, 7 percent. The range of increase in mineral manufacturing was less, from 8 percent for petroleum refining and cement to 11 percent for blast furnaces and steel works. Fertilizer, coke, and primary copper, lead, zinc, and aluminum all had 9 or 10 percent increases in the annual average. The big jumps in monthly figures took place in December (7 percent) for copper, lead, and zinc mining, smelting, and refining; February (about 10 percent) for anthracite and bituminous coal. Other increases were more gradual.[24]

Productivity.—Output per man-hour generally rose in coal and metal mining from 1950 to 1951. (No data were available for crude-petroleum production or nonmetallic mining.) Those increasing were bituminous coal and recoverable copper, each 1 percent, and anthracite and direct-shipping iron ore 8 percent. A decrease was experienced in labor productivity in terms of recoverable lead-zinc (5 percent) and primary refining of copper, lead, and zinc (7 percent). Mineral-manufacturing industries with increased output per man-hour were cement (6 percent), byproduct coke (2 percent), and beehive coke (9 percent). (For other mineral-manufacturing industries data were not available.)[25]

Health and Safety.—Disabling injuries in mining industries in 1951 declined as a portion of the total for all industrial groups from 3.69 percent in 1950 to 3.57 percent. Fatalities in mining industries rose, however, from 6.45 percent to 7.50 percent of those in all industries.[26] Fatality rates in mining rose largely because of the fatality-rate increase in coal mining—the result of an unusual number of major disasters. (Detailed discussion of health and safety statistics in mineral industries is found in the chapter on Employment and Injuries.)

PRICES AND COSTS

Prices of minerals in the United States were quite stable during 1951 because of the effects of price control. The Bureau of Labor Statistics monthly wholesale indexes moved only a point or two during the year, but the annual averages were generally well above those for 1950. Both coal and gas, however, averaged only about 2 percent above 1950. Petroleum and products monthly indexes only increased 1 percent during the year but the annual average was 7 percent above that for 1950. Iron and steel products and nonferrous metals both fell a point or two from January to December but on an annual basis were 9 and 19 percent, respectively, above 1950. Clay and gypsum products were unchanged during the year but their annual averages were up 8 and 12 percent, respectively. Fertilizer materials climbed 4 percent during the year, but the annual average was only 5 percent over 1950.

Wholesale price indexes of materials and equipment cost items did not rise significantly. Lumber fell 4 percent from January to December, and construction machinery and equipment and industrial chemicals only rose 1 percent each. The first two averaged about 10 percent each above 1950 values, but industrial chemicals were 19 percent above 1950.[27]

The 6- to 13-percent increase in annual average hourly earnings in mining and mineral manufacturing industries from 1950 to 1951 was not matched by increases in annual productivity. Thus, it may be said that unit labor costs increased from 1 to 3 percent (which would be one-third of 1 percent to 1 percent of output prices). Fortunately for these industries, the average price increases from 1950 to 1951 were about 10 percent, so labor costs generally fell as a fraction of sales for the year. Within the year, however, average hourly earnings increased much more than prices (which had their big jump in the last quarter of 1950), so quarterly operating profits were seen to fall during the year. The experience for individual industries differed widely, however.

TABLE 8.—Relative labor cost in mineral industries in the United States, 1950–51, percentage change in annual averages

Industry	Percentage change in—			
	Average hourly earnings [1]	Price [2]	Output per man-hour [3]	Unit labor cost as a percent of price

TRANSPORTATION

Rail and water transportation of minerals and mineral products grew with general industrial activity. However, mineral-product tonnage fell as a fraction of the total tonnage of all products carried both in the case of rail and of water transportation (*see* table 9). In the case of rail transportation, the decline in proportion was due to the less than average increase in rail haulage of bituminous coal. Iron ore hauled by rail increased 20 percent, the same as the increase for all tonnage.

These transportation data do not agree exactly with that submitted to the Bureau of Mines by its respondents, shown in the various commodity chapters (cement, coal, coke, fluorspar, fuel briquets, iron ore, petroleum, sand and gravel, slag, and crushed stone) because of slightly different reporting concepts and item and respondent coverage.

TABLE 9.—Rail and water transport of mineral products in the United States, 1950–51, in millions of short tons

Commodity	Rail [1]		Water [2]

FOREIGN TRADE AND INVESTMENTS

Imports.—The value of mineral imports for 1951 rose only 6 percent above that of the previous year because of a 7-percent decline in metals imports. All other major mineral categories registered increases from 23 percent for crude nonmetallics to 6 percent for fuels. Fuels were 35 percent of mineral imports. Metals and their ores and concentrates comprised 48 percent, nonmetallics 10 percent (nearly all in crude form) and other mineral imports, 7 percent. (*See* table 8 in the Statistical Summary chapter.)

Digitized by Google

Declines in mica, tin, lead, zinc, and nonferrous scrap were to a large extent responsible for strategic shortages in 1951. These were extreme cases of a general pattern of increased demand and emergency hoarding in all countries. Imports swelled in the last half of 1950 after the Korean outbreak, but increased foreign consumption and substantially uncontrolled prices greatly reduced the flows to this country of the most strategic items. The 1951 decline in residual oils and the modest increase in crude imports resulted from the world petroleum crisis following the Abadan seizure, which reduced petroleum imports significantly in the third quarter as Venezuelan petroleum products were diverted to Europe.

Exports.—Fuels, as usual, had overwhelming importance among mineral exports in 1951, comprising 85 percent of the total value. Of the remainder, metals came to 6 percent, nonmetallic minerals 8 percent, and other, 1 percent. (*See* table 8 in the Statistical Summary chapter.)

The great increase over 1950, which raised mineral exports to seven-eighths the value of mineral imports, also was due to fuels exports, which increased 79 percent in value. Great percentage export value increases also took place in metals, crude metallic minerals, and nonmetallic manufactures (141, 55, and 47 percent, respectively), but crude nonmetallic exports increased little (11 percent).

Tariffs.[28]—*Escape-Clause Actions.*—Application for tariff relief under the "escape-clause" procedure outlined in Executive Order No. 10082 (1949) resulted in an adverse action for the lead industry. Escape-clause applications with respect to lead-bearing materials, lead, and lead scrap brought (early in 1950) by the Emergency Lead Committee, New York, and the New Mexico Miners and Prospectors Association, were dismissed by the Tariff Commission on January 25, 1951, after preliminary hearings.

In June 1951 the Trade Agreements Extension Act of 1951 was passed. This law, which basically extends the authority of the President to enter into trade agreements with other countries, now includes an escape clause and "peril-point" amendment. The peril-point amendment appeared originally in the Trade Agreements Extension Act of 1948 but was repealed, along with the entire act of 1948, by the Extension Act of 1949. Both the escape clause and the peril-point amendment provide industries with the opportunity to seek protection from injurious foreign competition. The peril point allows the industry to seek protection from any adverse change of rates as a result of impending negotiations, and the escape clause affords the industry the means of seeking relief as a result of a past tariff concession.

Congressional Actions.—The import duty on all scrap metal was suspended by the Congress for 1 year beginning June 30, 1951. Also, by act of Congress, effective April 1, 1951 (until February 15, 1953, or the end of the emergency period, whichever occurs first), the import duty on various copper items was suspended. This suspension of the duty on copper ores, concentrates, and articles containing copper was to remain in effect so long as the average monthly market price of copper was 24 cents or more per pound delivered Connecticut Valley. If the average domestic market price of electrolytic copper,

[28] This section was prepared by H. E. Striner, Bureau of Mines.

Digitized by Google

delivered Connecticut Valley, was below 24 cents per pound for 1 calendar month, the Tariff Commission within 15 days after the end of that month was to advise the President of this situation. The President then had to revoke the suspension by proclamation. This proclamation was to be issued not later than 20 days after the advising action by the Tariff Commission.

International Agreements.—Multilateral reciprocal tariff negotiations undertaken at Torquay, England, in September 1950 were completed in April 1951. These negotiations, conducted under the provisions of the General Agreement on Tariffs and Trade (usually referred to as GATT), resulted in tariff bindings and reductions on a number of mineral items by the United States. A list of these items includes various barium compounds, magnesium salts and compounds, all potash salts, sodium compounds, tellurium compounds, coal-tar compounds, cobalt compounds, iodine (resublimed), zinc, and lead ores, concentrates and compounds, magnesium and magnesium compounds, manganese, phosphorus, mineral-earth pigments, barites or lampblack, potassium compounds, strontium compounds, thorium compounds, tin compounds, magnesite, clay of various sorts, bentonite, feldspar, clays, silica, crude fluorspar containing over 97 percent of calcium fluoride, mica, talc, granite, pig iron, molybdenum, ferromanganese, manganese-silicon, various ferrous compounds, chrome, titanium, boron, vanadium, calcium metals, zirconium metals, aluminum metal and alloys, and bismuth.

Foreign Investment.—In 1951, net direct investment capital movements from the United States to other countries plus reinvested earnings and other changes (*see* table 10) increased the total investment abroad in mining and smelting 17 percent, in petroleum 9 percent, and in all industries 11 percent. The cumulative net mineral investment abroad remained at 38 percent of net investment abroad in all industries.

Net capital movements from the United States to other countries in 1951 for petroleum and mining and smelting fell 42 percent from 1950 and amounted to only 37 percent of such investment for all industries (in 1950 they had been 54 percent of the total). The total for all industries of such investment flows declined 15 percent compared with 1950. The major exceptions to this general decline were Brazil, Peru, and Chile, for which modest increases took place for mineral industries and for all industry.

Canada accounted for 133 percent of the net flow of United States investment abroad in petroleum ventures in 1951 and 36 percent of mining and smelting investment flows. Chile and Peru together accounted for another 54 percent of the latter flows. Of the areas of greatest cumulative net United States investment abroad in petroleum, Venezuela and the Middle East (25 and 20 percent, respectively), the former suffered a slight decline in 1951. On the other hand, the countries with the greatest cumulative net investment in mining and smelting, Chile and Canada (31 and 30 percent, respectively), each enjoyed increases in mining and smelting investment flow in 1951 and together accounted for 66 percent of the 1951 total.

[2] Includes industries not shown separately.
[3] "Other changes" consist of adjustments caused by revaluation of properties, transfer of assets from one country to another, profit or loss on liquidations, and other technical adjustments. The net of such changes in 1951 were as follows (in millions of dollars): Mining and smelting, all areas, 32 (Peru, 33; other Latin American Republics, −1; Western European countries, −1; all other countries, 1); Petroleum, all areas, 16 (Panama, −7; United Kingdom, 6; Other Western European countries, 11; Middle East and "all other countries," 6); All industries, all areas, 22 (Canada, −28; Panama, −7; Peru, 33; other Latin American Republics, 1; United Kingdom, 6; Other Western European countries, 10; Middle East and "all other countries," 7).
[4] Included in totals.
[5] Less than $500,000.
[6] Includes countries not shown separately above.
[7] Includes Aden, Bahrein Islands, Egypt, Iran, Iraq, Israel, Jordan, Kuwait (including neutral zone), Lebanon, Saudi Arabia (including neutral zone) and Syria.

The flow of gross petroleum capital expenditures for foreign facilities was 13 percent of domestic gross and was 250 percent of net petroleum investment abroad in 1951.[29] (Comparable gross figures for other mineral industries not available.) The flow of net investment abroad for all industries in 1951 was 2.6 percent of domestic net investment flow (which is computed by subtracting the sum of capital consumption allowances and private residential construction from gross private domestic investment).

Economic Cooperation Administration.—The Economic Cooperation Administration purchased $14.5 million worth of strategic minerals[30] for the National Stockpile during 1951, of which 92 percent was covered by counterpart funds. During the same period it committed $68.2 million for prospecting, developing, and expanding production

[29] Work cited in footnote 15, p. 20.
[30] Plus small amount of nonmineral products.

Digitized by Google

of strategic minerals in "ECA areas," raising the cumulative total to $109 million. Ninety percent of the 1951 total was from counterpart funds. The repayment of the total of these advances was to be made in minerals for the Stockpile, and usually options for additional Stockpile purchase were involved as well.[31]

The first contract guaranteeing the convertability of receipts from licensing patents, processes or techniques without an accompanying cash or "hard" investment (as provided for in the 1950 amendments to the Economic Cooperation Act) was made in the first quarter. Informational-media-receipts-convertability guarantees were continued and constituted an important contribution to technical assistance programs.

Mineral products constituted 20 percent of procurement authorizations for European countries in 1951, about 55 percent of which was for fuels. This equaled the value of 15 percent of United States coal exports during the year.

DEFENSE MOBILIZATION

Defense Production Act.—The Defense Production Act of 1950 was amended and renewed as Public Law 96, 82d Congress, on July 31, 1951. The same powers as the act originally contained were continued in essentially unmodified form as far as minerals expansion assistance was concerned, except that subsidy granting powers were clarified. A number of changes permitting adjustments of price ceilings were added, which liberalized that treatment, and provisions covering materials and equipment allocations to small businesses and other provisions covering small business problems had some impact on minerals firms. The administration continued to request review of price control sections of the act by Congress throughout the remainder of the year.

Defense Minerals Administration.—During 1951 the Defense Minerals Administration developed programs stating requirement needs and supply deficiencies of strategic minerals and instituted supply projects to make up the indicated shortages. DMA also contracted with private companies on a sharing basis to stimulate exploration designed to provide a long-run base of strategic minerals reserves. Maintenance of existing production was assisted by arranging priorities for scarce manpower, materials, and equipment needed to keep mines operating at maximum efficiency. Among the types of assistance recommended under provisions of the Defense Production Act to expand supply were accelerated tax amortization, conditional procurement contracts, fixed-price contracts, subsidies, loans, advances, loan guarantees, and access roads.

The agency recommended such projects to the Defense Production Administration for certification to the various operating agencies to carry out. Accelerated tax amortizations were certified to the Bureau of Internal Revenue. Loans were certified to the Reconstruction Finance Corporation for final development of terms. Procurement contracts and advances were certified to the General Services Administration for final negotiation, execution, and administration. Access roads were directly recommended to the Bureau of Public Roads for survey and construction.

[31] U. S. Department of Defense, Munitions Board, Stockpile Report to the Congress: July 23, 1951 and January 23, 1952.

Digitized by Google

During 1951 the budget estimates indicated that the gross commitments required under DMA programs would be over $6 billion, but it was obvious that the cost to the Government would never be more than a fraction of that amount. This led to an important development in Government accounting, estimation of the financing necessary to meet the expected cost of such assistance to the Government. When the budget was submitted under this concept, the "probable ultimate net cost," a prudently ample obligation limit requested for the fiscal year beginning in July 1951, was below the original $2 billion authorization limit of the Defense Production Act as amended.

Another section of DMA work considered to be to a large degree completed during 1951 was recommendation of accelerated tax-amortization projects. This was natural because of pressure for early construction starts under the program and the fact that the largest projects came in early.

Defense Materials Procurement Agency and Defense Minerals Exploration Administration.—On August 28, 1951, the President established the Defense Materials Procurement Agency and transferred the authority of the Secretary of the Interior for emergency mineral assistance responsibilities to the General Services Administrator under Executive Order 10281. The General Services Administrator delegated back to Interior (September 14) the exploration assistance responsibilities (and budgets), which were of a long-run rather than an emergency nature. To carry out these duties, the Secretary of the Interior organized the Defense Minerals Exploration Administration (November 20) with personnel transferred mostly from the DMA Production Expansion Division. The General Services Administrator, under Budget Bureau orders of determination and disposition, incorporated most of the other DMA personnel in the Defense Materials Procurement Agency on October 28 along with the minerals personnel of the ECA Materials Development Division in December.

With the assistance of the General Services Administration the DMPA carried out the functions previously performed by DMA (except the delegated exploration), that is, keeping minerals programs up to date and analyzing and negotiating domestic and foreign expansion assistance projects for recommendation to the Defense Production Administration.

The Defense Minerals Exploration Administration continued to carry out (as DMA previously did) the analysis of exploration proposals, and the negotiation and administration of exploration-expense-sharing contracts. Early in 1951, DMA had obtained approval of and issued Mineral Order 5, which listed three sharing exploration percentages (50, 75, and 90) under which strategic minerals were grouped and also specified other regulations and instructions, which were also subsequently followed by DMEA. By December 31 DMA and DMEA had received 1,174 applications for exploration assistance, executed 197 contracts, and otherwise disposed of 437 applications.

Price Controls.—Price control of minerals in the United States began with a series of industry meetings in January at which it was apparent that the prices of copper, lead, and zinc had already risen enough to sustain considerable pressure from increases in costs and foreign

302512—54——3

Digitized by Google

metals prices. The latter, however, became especially bothersome through the year. Much of the industry felt that the New York futures market should be closed and all tariffs removed if the price were to hold. The market was closed.

Foreign prices of minerals continued to climb after United States prices were frozen until they were later frozen at higher levels or never even formally controlled. The Chilean Government was in no mood to be "regulated" by the Office of Price Stabilization when some copper was selling to certain Europeans at twice the United States ceiling. After Chilean price negotiations were settled, the United States agreed in May to establish an import price ceiling for copper 3 cents above the 24.5 cent domestic ceiling. Import declines of lead and zinc led to 2-cent increases in their ceiling prices in October.

Concern over supplies of ferroalloy metals led to an unusual price-control ceiling. In May domestic tungsten was guaranteed a $63-per-unit price for 4 years which was substantially higher than an adjusted freeze price would have been. This action was taken as an effort to afford sustained encouragement to the domestic industry. Price controls were dropped altogether, for example, on cobalt, columbium, titanium, and nickel in an effort to encourage increased supply.

Other Defense Organizations.—There were no other defense agency reorganizations of particular significance for minerals industries. The reorganizations in the Office of Defense Mobilization, Defense Production Administration, National Production Authority, and the Economic Stabilization Agency's suborganizations were all essentially internal adjustments to rapid, administrative expansion. An Executive order of January 3, 1951, transferred the coordinating authority in the materials field from the National Resources Planning Board to the Defense Production Administration. That Administration organized the interagency Vital Materials Coordinating Committee to perform the functions of coordinating expansions of supply, distribution of available quantities, and restrictions of nonessential uses. The Small Defense Plants Administration was under fire throughout 1951 but maintained its independence and enlarged its scope of function.

The Defense Solid Fuels Administration and the Petroleum Administration for Defense continued through 1951 with their operations, expanding rapidly at the same time, especially in the first half of the year. Their major assistance projects were for accelerated tax amortization and a heavy part of their workload was as a claimant agency for materials, manpower, and equipment for the industries within their scope.[32]

The Office of International Trade applied its export controls to all strategic minerals, for which there were several gradations of control from closed, quantitative, restrictive, to open end (which were freely licensed but watched closely).

National Strategic Stockpile.[33]—The accelerated activity connected with the National Strategic Stockpile initiated in 1950 was continued throughout 1951 to the extent allowed by supply conditions. Fifty-

[32] *See* Annual Reports of the Secretary of the Interior, 1951 and 1952, and press releases of the agencies.

Digitized by Google

four percent of the obligations incurred over the 5½ years of the Stockpile were incurred in 1951. Likewise, 41 percent of the cumulative expenditures up to December 31 took place in that one year. In November there were moderate increases in total obligational authority and cash appropriated to stay ahead of the 1951 program of incurring obligations.

Total Stockpile objectives were raised during 1951 from $8,870 million to $9,298 million, a net figure resulting from both increases and decreases. As a result of emergency shortages, the President authorized release of $40 million worth of aluminum, copper, and lead from the Stockpile inventory.

Specifications were revised for asbestos, bauxite, bismuth, cobalt, quartz crystals, fluorspar, graphite, iridium, kyanite and mullite, lead, platinum, and tungsten powder. The only reclassification of commodity during 1951 was the shift of iodine from Group II to Group I, indicating that purchases from general sources were to be reopened.

The Export-Import Bank established $38 million of credits abroad during 1951 to assist production of manganese and tungsten concentrates for the National Stockpile and had several millions more of credits under consideration at the year end for the same purpose.

The Commodity Credit Corporation through December 31, 1951 exchanged some of its agricultural commodities for $33 million worth of industrial diamonds, chromite, and manganese produced abroad, which were then purchased by General Services Administration for the Stockpile.

TECHNOLOGY

Mining.[34]—Improvements were made in mining technology in all fields of the mineral industries during 1951, but no outstanding innovations were reported.

In the bituminous-coal industry the trend was toward increased mechanization, with a resultant increase to 7.04 tons output per man-shift from 6.77 in 1950.

Experiments to adapt longwall mining to American conditions were begun at several bituminous-coal mines; European longwall machines were imported for the tests. The increasing scarcity of high-quality coking coals in the United States makes these experiments particularly important. Nearly half of our coking coal is now lost in mining; the success of the longwall mining experiments would lead to a substantial increase in the percentage of extraction.

A successful application of block caving was made in the anthracite mines; the tonnage per man-shift was increased several fold over conventional methods.

The practice of roof bolting was greatly extended both in coal and metal mines. Roof bolting permits freer use of mechanical equipment, which, in turn, increases the tons per man-shift.

In underground metal-mining, improvements were made in drilling and blasting practices. Jumbos and jackleg drill supports continued to replace drill columns. Improvements in tungsten carbide bits have permitted drilling a blast hole with a single piece of steel.

[34] This section was prepared by E. D. Gardner, chief mining engineer, Bureau of Mines.

Digitized by Google

This practice, together with jumbo-mounted drills, has reduced drilling costs. Millisecond blasting was introduced in some mines.

Diesel trucks continued to replace track haulage at mines where conditions favored the change. The use of belt haulage underground was extended. More tractor-mounted loading equipment, such as that used in surface excavations, also was introduced underground.

A successful experiment was made with hydraulic hoisting through pipes at one mine. A shaft was sunk through quicksand in the New Mexico potash field by the freezing method. This was the first successful application of freezing in shaft sinking in America—at least in the past 3 decades. Plans were drawn for longwall mining of potash at one mine, and pillar extraction was begun at two others.

The economic ratio of stripping to ore increased in all fields of mining so that some deep (over 350 feet) deposits that previously would have been exploited by underground mining were being mined as open pits.

Milling and Metallurgy.[35]—*Beneficiation.*—The most spectacular developments in mineral dressing have been in the taconite and other iron ores of the upper lakes area. As an instance, the Reserve Mining Co. let $75 million contracts for construction of a 2,500,000-ton-per-year concentrates plant at Beaver Bay, Minn. It began erecting a 300,000-ton-per-year pilot plant for magnetic concentration and pelletizing of concentrate. Oliver Mining Co., Erie Mining Co., and Pickands Mather & Co. were doing similar things. Cleveland Cliffs Iron Co. had put into commercial operation a Dutch State Mines "cyclone" plant for concentrating iron sands at the Buckeye mine of M. A. Hanna & Co., and another was started at the Holman mine.

Manganese ores of the Three Kids mine, near Las Vegas, Nev., were to be concentrated in a 1,000-ton-per-day concentrator under construction. The Bureau of Mines began constructing a pilot plant at Boulder City, Nev., for flotation and hydrometallurgical treatment of ore from the Artillery Peak mine in Arizona. Other concentrators for Cuyuna-range manganese slates and other low-grade ores were contemplated to produce concentrate between 20 and 30 per cent manganese that could then be treated by several hydrometallurgical processes.

The mill of Calera Mining Co. (Howe Sound) at the Blackbird mining district of Idaho began producing copper concentrate and cobalt concentrate from 1,000 tons of ore daily. The copper was to be smelted at Garfield and the cobalt recovered by a hydrometallurgical process in a plant under erection at Garfield, Utah. Cobalt-nickel-copper-iron sulfide middlings made by National Lead Co. at Fredericktown, Mo., during the milling of a lead ore are to be treated in a similar hydrometallurgical plant using the Chemico process. This was also to be done by the Lynn Lake mine of Sherritt-Gordon in Manitoba where a 50-ton-per-day-pilot-plant was in operation.

In milling the most expensive step—grinding—was being intensively improved and cheapened. Several installations of new high-speed, large-diameter rod mills had been breaking records.

In concentration the Humphreys spiral and the Dutch cyclone were becoming very popular and promising further developments in future years. Electrostatic separation of mixed concentrates made from

[35] This section was prepared by O. C. Ralston, chief metallurgist, Bureau of Mines.

Digitized by Google

placer and beach sands had won definite place in large mills in Florida and was included in the testing work done on many of the new complex ores under development.

The Mardun disintegrator, developed in a small desert plant of northern Arizona, was further developed at the Salt Lake Experiment Station of the Bureau of Mines. A mixture of strong and weak minerals is stirred in a rotating device of controllable speed at a rate that will reduce the soft mineral to dust and leave the strong mineral grains only slightly abraded. The original plant in Arizona treated a sandstone containing soft copper carbonates. The apparatus is simple and appears to offer great promise.

Metallurgy.—As mentioned above, hydrometallurgy as an adjunct to beneficiation is finding new fields. The Artillery Peak manganese dioxide ore is very fine grained, and flotation is successful only on the more granular material produced when the ore is ground. The tremendous reserves of siliceous manganese ores and the manganese slates of the Cuyuna range in Minnesota cannot be beneficiated to Metallurgical Grade but can be concentrated with acceptable recovery if 20 to 25 percent Mn concentrate is made. Then hydrometallurgy would take over.

Uranium is recovered by hydrometallurgical methods from most of the ores of the Colorado Plateau, and new proposals were under way for recovering the small amounts of uranium in gold ores and phosphate pebble, both of which are worked in such large tonnages that the total of available uranium in the lean material is not inconsiderable.

Titanium was a favorite research subject during the year, and organization of production went forward. The Titanium Metals Corp. of America, jointly owned by National Lead Co. and Allegheny Ludlum Steel Co., was awarded a contract for producing 10 tons of titanium sponge daily and began construction and operation. Du Pont de Nemours & Co. were also very active in production, but moved more slowly and cautiously. The Bureau of Mines continued improvements on the Kroll process used by both of the above, and the literature was replete with articles on the alloys of titanium and their properties and potential usefulness. The Van Arkle process of refining titanium by the tetraiodide process was intensively discussed, and the New Jersey Zinc Co. set up a small plant to produce highly refined titanium for the use of experimenters on alloys.

There was great interest in zirconium, also sparked by the Bureau of Mines, but the curtain of secrecy surrounding its use as a structural material in the raising of atomic power, hindered to some extent the free exchange of information about its extraction, refining, fabrication, and alloying. Recovery of the hafnium associated with zirconium also was begun.

Lead, zinc, and cadmium were recovered at higher rates than before.

The germanium content of zinc ores was under intense scrutiny, and the Eagle Picher Co. at Joplin, Mo., produced much of the metal used in transistors and other electronic tubes. Selenium for rectifiers was in short supply, and many were seeking a further supply. Utah was found to be the most important area for selenium supplies, and a considerable amount was noted in Mexico.

Fuels.[36]—*Synthetic Liquid Fuels.*—The first demonstration-scale Fischer-Tropsch (gas-synthesis) plant in this country to produce synthetic liquid fuels from coal was completed and tested by the Bureau of Mines in 1951. Technological advances were made in developing the coal-hydrogenation process, in producing more durable catalysts for this and the gas-synthesis process, in reducing oil-shale mining costs using Bureau-developed equipment and in retorting oil shale and refining shale oil to usable products. In laboratories, pilot plants, and demonstration-scale equipment the Bureau added much information for industry in evaluating synthetic fuels processes. Reduction of costs of producing synthesis gas was also achieved.

Petroleum.—There were no outstanding advances in petroleum technology; but in 1951 manufacture of "petrochemicals" increased markedly over 1950, and several units of the platforming process were started in operation.

Coal.—The Bureau of Mines conducted research to improve the safety and efficiency of coal mining by studies and tests of mechanical mining equipment for both bituminous coal and anthracite, including the introduction of a German coal planer to long-wall mining of thin-bed coal. Coal preparation and utilization research and developments included successful testing of a heavy-medium pilot plant to separate close-gravity fractions of coal and refuse, improvements in the Bureau-developed kerosine flotation process, preparation of ultraclean coal for electrodes, testing and developing special types of combustion equipment, study of factors affecting the quality of coke and the behavior of coal in coke ovens, and assistance in the design of the first commercial plant utilizing the Bureau-developed process of fluidized drying and carbonization of noncoking coals. The Bureau's research work on coal and synthetic liquid fuel from coal in 1951 was summarized in information circulars 7647 and 7663.[37]

Private Research.—The Research and Development Board of the Department of Defense had the Bureau of Labor Statistics prepare a report on private industrial research in 1951 based on a sample (which covered most of American industrial scientists) of 1,934 companies including 49 petroleum firms and 49 primary metals companies. The report showed that, out of 89,851 research engineers and scientists employed by all industries, 5.5 percent were employed by petroleum refining and 1.9 percent by primary metal industries in January 1952. The cost of research to petroleum refining in 1951 was $93 million, 5.2 percent of that for all industry, and primary metal industries spent $34 million. Only 3.1 percent of the expenditure by petroleum refining was financed by the Federal government, and 9.5 percent in primary metal industries—much lower than the 47.0 percent of all industries.[38]

WORLD REVIEW

World Production.—World production increased for virtually all major minerals from 1950 to 1951 and for many of them reached the highest level of annual ever attained.

Crude petroleum rose 13 percent, and lignite increased about 14 percent. Coal production increased only 5 percent. Inasmuch as coal constitutes about half the world energy sources (in terms of coal equivalents), the increase in world energy consumption was only 9 percent, a 7.5-percent-per-capita increase. The 8 largest European coal producing countries all registered modest output increases, but Western Germany production increased about 7 percent.

TABLE 11.—Comparison of world and United States production of principal minerals and metals, 1950–51

Most nonmetallic minerals (other than fuels) had record years of output in 1951. This was also true of petroleum and natural gas. The only major metals, however, with a 1951 historical peak were iron ore, manganese, zinc, chrome, and antimony. (The greatest world production years for most other metals was 1943; 1941 for tin and mercury; 1940 for gold; and 1937 for silver.)[39]

World Prices and Stocks.—Coal prices rose substantially in a few countries from June 1950 to August 1951, Poland by 90 percent and Western Germany by 45 percent, but only small increases were realized in most countries because of price controls. Stocks of coal increased in most of the major producing countries but fell in France, Belgium and Japan.[40]

Petroleum-products prices also rose only moderately because output rose readily with demand.[41] Stocks were also able to rise during the year.[42] The largest price increases were those for fuel oils which rose an average of 15 percent above 1950.

World prices of native sulfur [43] continued to increase wildly where there was no price control, but pyrites prices rose less because of a greater relative increase in production (9 percent compared to 2 percent for native sulfur).

The London tin price rose to £1,615 in February and fell to £805 by August. Nevertheless, the sixth meeting of the International Tin Study Group held in Rome during September did not consider an international agreement in their discussions of long- and short-run cooperation.[44]

Aluminum prices rose only modestly in all countries under the moderating influence of large increases in output by the United States and Canada.[45] World trade in aluminum expanded along with the large increase in Canadian output, the world's largest exporter.[46]

Prices of iron ore, scrap and pig iron [47] rose considerably in all important countries but generally less than prices of nonferrous metals or ferroalloy metals. Scrap rose much more than iron ore or pig iron because its supply was less elastic.

International Cooperation.—Of all the intergovernmental cooperative efforts that affected minerals industries, the International Materials Conference was the most important. The foreign ministers of France, the United Kingdom, and the United States published a joint declaration on January 12, 1951, stating their agreement to propose international commodity groups to certain other governments. Four committees (out of seven created) covered minerals: The Copper, Zinc, and Lead Committee; the Manganese, Nickel, and Cobalt Committee; the Tungsten and Molybdenum Committee; and the Sulfur Committee. The countries that joined the original three on commodity committees were: The other members of the British Common-

wealth; all the other countries of Western Europe (except Ireland, Denmark, and Greece); and Japan, Mexico, Cuba, and all the South American countries (except Venezuela, Colombia, Ecuador, and Paraguay). Only Western Germany and Canada were on all the mineral committees, in addition to the original three nations. The committee membership included over 85 percent of the Free World production and consumption of the scarce minerals involved.

By the third quarter (July 1951), three months after beginning their work, the Tungsten-Molybdenum and Sulfur Committees had made recommendations for quarterly allocations of their commodities. By the fourth quarter, the other two mineral committees had agreed upon quarterly allocations of their minerals.[48]

The emergency allocations were designed to achieve an orderly and equitable distribution of available supplies, recognizing needs for defense, strategic stockpiling, and essential civilian consumption. The committees endeavored not to interfere with normal channels of trade and made no recommendations for allocation by source. The quotas were merely limits on exports and imports, which permitted countries, within those limits, to buy from or sell to any countries of the Free World. The methods of distribution and control of prices within a country were matters for determination by that country. Copper was the most widely restricted commodity and the first to receive attention by the Organization for European Cooperation. In September 1951, the OEEC adopted a list of 211 articles for which it was recommended that the use of copper, and alloys containing over 40 percent copper, should be prohibited. Most of the major consumers also imposed restrictions on the other allocated minerals.

Although the immediate direct effect on the United States minerals industries was not great, a very important long-run development in international cooperation was the signing on April 18, 1951, of the treaty constituting the European Coal and Steel Community, commonly known as the Schuman Plan (after Robert Schuman, Minister for Foreign Affairs for France). The parties to the treaty were France, the German Federal Republic, Italy, Belgium, the Netherlands, and Luxembourg. The major positive and direct effects of the treaty were removal of trade barriers among the party nations covering iron, ferroalloy and steel-mill products, their raw materials (except limestone), and fuels. Subsidies, restrictive practices, and discriminations were also to be eliminated, and it was the aim of the parties to achieve the lowest prices feasible.

Statistical Summary of Mineral Production

By Robert E. Herman [1]

INTRODUCTION

THIS CHAPTER, in line with corresponding chapters in earlier editions of the Minerals Yearbook, contains summary statistical data on mineral production in the United States. However, it also includes a table summarizing the foreign trade of the United States in minerals and mineral products (table 8); in Minerals Yearbooks for earlier years, a table of this nature has usually been carried in the Review of the Minerals Industries chapters.

PRODUCTION

The tables in this section summarize the statistics on mineral production in continental United States, that is, the 48 States and the District of Columbia (tables 1–3); in each of the individual States (tables 4 and 5); in the Territories of the United States (table 6); and in possessions and other areas administered by the United States (table 7).

Mineral production may be measured at any of several stages of extraction and processing; for example, see table 2 of the Copper chapter of this volume. However, the term "mineral production" usually refers to minerals in the form in which they are first extracted from the ground but customarily includes, for some minerals, the product of auxiliary processing operations at or near mines—such as sizing and cleaning, in the case of coal, and concentrating, in the case of metallic ores.

Because of inadequacies in the available statistics, some series deviate from the foregoing definition. In particular, the limestone, cement rock, and clay that are processed into cement are reflected in the series on cement rather than being included in their originally extracted form; similarly, limestone used for lime is reflected in the series on lime rather than that on stone. The quantities of gold, silver, copper, lead, zinc, and tin are recorded on a mine basis—that is, as the recoverable content of ore sold or treated; the values assigned to these quantities, however, are based on the average selling price of refined metal, not the mine value. Mercury is measured in the form of recovered metal and valued at the average New York price for metal.

A number of additional deficiencies in a previously maintained series (which covered the period 1880–1948) were eliminated with revisions

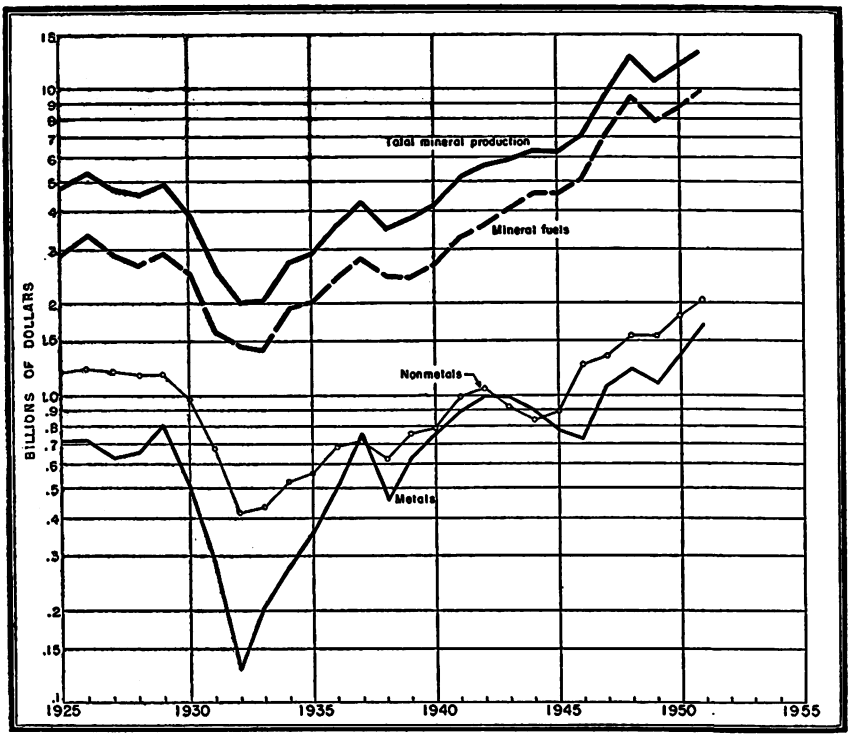

FIGURE 1.—Value of mineral production in continental United States, 1925–51.

that are described in the Statistical Summary chapter of Minerals Yearbook, 1949.

The weight or volume units shown are those customary in the particular industries producing the respective products. No adjustment has been made in the dollar values for changes in the purchasing power of the dollar.

TABLE 1.—Value of mineral production in continental United States, 1925–51, by mineral group [1]

[Millions of dollars]

Year	Nonmetallic			Metallic	Grand total	Year	Nonmetallic			Metallic	Grand total
	Fuels	Other	Total				Fuels	Other	Total		
1925	2,905	1,192	4,097	715	4,812	1939	2,420	757	3,177	631	3,808

Rutile	do	9,907	647	10,559	490	[11]	[11]	[11]	[11]
Tungsten concentrate	short tons, 60-percent WO_3 basis	4,033	6,355	2,765	4,377	4,807	8,157	6,265	22,937
Zinc (recoverable content of ores, etc.)	short tons	629,955	167,974	593,201	148,913	623,369	178,667	681,188	249,331
Undistributed: Magnesium chloride for magnesium metal, platinum-group metals (crude), vanadium, zirconium concentrate, and minerals whose value must be concealed for particular years (indicated in appropriate column by footnote reference 11)			10,466		6,671		10,216		17,755
Total metals			1,219,000		1,101,000		1,351,000		1,670,000
Grand total mineral production			12,273,000		10,580,000		11,855,000		13,524,000

[1] Production as measured by mine shipments or mine sales (including consumption by producers), except that fuels and the following additional minerals are strictly production: Gypsum, iodine, magnesite, pyrites, bauxite, and mercury. Excludes uranium ores and monazite.

[2] Includes small quantity of anthracite mined in States other than Pennsylvania.

[3] Final figure. Supersedes preliminary figure given in commodity chapter.

[4] Excludes sharpening stones, value for which is included with "Nonmetallic minerals, undistributed."

[5] Weight not recorded.

[6] Excludes clays sold or used for cement as follows: 1948—6,362,000 short tons, $4,320,000; 1949—6,676,000 tons, $4,573,000; 1950—7,080,000 tons, $5,574,000; 1951—7,804,000 tons, $8,052,000.

[7] Value included with "Nonmetallic minerals, undistributed."

[8] Revised figure.

[9] Excludes production from Wyoming, value for which is included with "Nonmetallic minerals, undistributed."

[10] Excludes abrasive stone, bituminous limestone, bituminous sandstone, and ground soapstone, all included elsewhere in table. Also excludes limestone for cement and lime.

[11] Value included with "Metals, undistributed."

[12] Columbite and tantalite production not differentiated and given under tantalum concentrate.

[13] Less than 0.5 ton.

TABLE 3.—Minerals produced in continental United States and principal producing States in 1951

Rank in value	Mineral	Principal producing States	
		In order of quantity	In order of value
	Abrasive stone:		
67	Grindstones and pulpstones	Ohio, West Virginia, Washington	Rank same as for quantity.
82	Millstones	Not available	North Carolina.
75	Pebbles (grinding)	Wisconsin, Minnesota, Texas, North Carolina	Minnesota, Wisconsin, Texas, North Carolina.
78	Sharpening stones	Arkansas, Indiana, New Hampshire, Ohio	Arkansas, New Hampshire, Indiana, Ohio.
76	Tube-mill liners (natural)	Minnesota, North Carolina, Wisconsin	Rank same as for quantity.
49	Antimony ores and concentrates	Idaho, Nevada, Washington, Montana	Idaho, Washington, Nevada, Montana.
66	Aplite	Virginia	Rank same as for quantity.
42	Asbestos	Vermont, Arizona, Georgia, North Carolina	Do.
36	Asphalt (native)	Texas, Alabama, Oklahoma, Kentucky	Texas, Utah, Alabama, Kentucky.
32	Barite (crude)	Arkansas, Missouri, Nevada, Georgia	Arkansas, Missouri, Georgia, Nevada.
27	Bauxite	Arkansas, Alabama, Georgia	Rank same as for quantity.
70	Beryllium concentrates	New Mexico, South Dakota, Colorado, New Hampshire	Do.
24	Boron minerals	California	Do.
21	Bromine	Texas, Michigan, California, West Virginia	Michigan, Texas, California, West Virginia.
74	Brucite	Nevada	Rank same as for quantity.
39	Calcium-magnesium chloride	Michigan, West Virginia, California, Ohio	Michigan, California, West Virginia, Ohio.
71	Carbon dioxide (natural)	New Mexico, California, Utah, Oregon	New Mexico, California, Oregon, Washington.
4	Cement	Pennsylvania, California, Texas, New York	Rank same as for quantity.
62	Chromite	California, Oregon	Do.
12	Clays	Ohio, Pennsylvania, Georgia, California	Georgia, Pennsylvania, Ohio, Missouri.
2	Coal:		
	Bituminous	West Virginia, Pennsylvania, Kentucky, Illinois	Rank same as for quantity.
	Lignite	North Dakota, Montana, South Dakota, California	Do.
	Pennsylvania anthracite	Pennsylvania	Do.
65	Cobalt (in ores, etc.)	Pennsylvania	Do.
7	Copper (in ores, etc.)	Arizona, Utah, New Mexico, Montana	Do.
29	Diatomite	California, Nevada, Oregon	Do.
72	Emery	New York	Do.
83	Epsomite	Washington	Do.
44	Feldspar (crude)	North Carolina, Colorado, South Dakota, New Hampshire	North Carolina, New Hampshire, South Dakota, Colorado.
25	Fluorspar	Illinois, Kentucky, New Mexico, Colorado	Rank same as for quantity.
55	Garnet (abrasive)	New York, Idaho, Florida	Do.
64	Gem stones	Not available	Oregon, California, Texas, Washington.
17	Gold (in ores, etc.)	South Dakota, Utah, California, Nevada	Rank same as for quantity.
61	Graphite:		
	Amorphous	Rhode Island	Do.
	Crystalline	Texas, Alabama	Do.
22	Gypsum (crude)	Michigan, New York, Texas, Iowa	Do.
53	Helium	Texas, Kansas	Do.
52	Iodine	California	Do.
3	Iron ore (usable)	Minnesota, Michigan, Alabama, Utah	Minnesota, Michigan, New York, Alabama.
59	Kyanite	Virginia, South Carolina	Rank same as for quantity.
11	Lead (in ores, etc.)	Missouri, Idaho, Utah, Colorado	Do.
14	Lime (open-market)	Ohio, Pennsylvania, Missouri, Illinois	Do.
58	Lithium minerals	South Dakota, California, North Carolina, Arizona	Do.
41	Magnesite (crude)	Washington, Nevada, California	Do.
35	Magnesium chloride (for magnesium metal)	Texas	Do.
30	Magnesium compounds from sea water and brines (except for metal).	California, Michigan, New Jersey	Michigan, California, New Jersey.

302512—54——4

TABLE 3.—Minerals produced in continental United States and principal producing States in 1951—Continued

Rank in value	Mineral	Principal producing States	
		In order of quantity	In order of value
37	Manganese ore	Montana, Arkansas, Nevada, New Mexico	Rank same as for quantity.
38	Manganiferous ore	Minnesota, New Mexico, Montana, Arkansas	Do.
46	Manganiferous residuum	New Jersey	Do.
	Marl:		
69	Calcareous	Michigan, Virginia, Wisconsin, Indiana	Michigan, Virginia, New York, Nevada.
68	Greensand	New Jersey	Rank same as for quantity.
50	Mercury	California, Nevada, Oregon, Idaho	Do.
48	Mica	North Carolina, New Hampshire, Georgia, Maine	North Carolina, Georgia, Pennsylvania, Arizona.
	Scrap	North Carolina, Georgia, South Dakota, Pennsylvania	Do.
	Sheet	North Carolina, Virginia, New Hampshire, Georgia	Rank same as for quantity.
19	Molybdenum (in ores and concentrates)	Colorado, Utah, Arizona, New Mexico	Do.
5	Natural gas	Texas, Louisiana, California, Oklahoma	Texas, California, Louisiana, Pennsylvania.
6	Natural gas liquids:		
	Natural gasoline and cycle products	Texas, California, Louisiana, Oklahoma	Rank same as for quantity.
	L-P gases	Texas, California, Oklahoma, Louisiana	Texas, California, Louisiana, Oklahoma.
73	Olivine	North Carolina, Washington	Rank same as for quantity.
51	Peat	Washington, New Jersey, Florida, Ohio	Michigan, Ohio, New Jersey, Florida.
60	Perlite (crude)	Nevada, New Mexico, Colorado, Oregon	Nevada, New Mexico, Colorado, California.
1	Petroleum (crude)	Texas, California, Louisiana, Oklahoma	Rank same as for quantity.
16	Phosphate rock	Florida, Tennessee, Idaho, Montana	Florida, Tennessee, Montana, Idaho.
80	Platinum-group metals (crude)	California	Rank same as for quantity.
18	Potassium salts	New Mexico, California, Utah, Michigan	Do.
45	Pumice and pumicite	California, New Mexico, Idaho, Colorado	California, New Mexico, Oregon, Idaho.
40	Pyrites	Tennessee, California, Virginia, Montana	Rank same as for quantity.
56	Quartz from pegmatites and quartzite	Washington, California, North Carolina, Connecticut	Do.
15	Salt (common)	Michigan, New York, Ohio, Louisiana	Michigan, New York, Louisiana, Kansas.
9	Sand and gravel	California, Michigan, New York, Illinois	California, Pennsylvania, Ohio, Michigan.
34	Sand and sandstone (ground)	Illinois, New Jersey, West Virginia, Ohio	Illinois, West Virginia, New Jersey, Ohio.
20	Silver (in ores, etc.)	Idaho, Utah, Montana, Arizona	Rank same as for quantity.
26	Slate	Pennsylvania, Vermont, New York, Georgia	Pennsylvania, Vermont, New York, Virginia.
31	Sodium carbonate (natural)	California, Wyoming	Rank same as for quantity.
43	Sodium sulfate (natural)	California, Texas, Wyoming	Do.
8	Stone	Pennsylvania, Ohio, Michigan, Illinois	Pennsylvania, Ohio, New York, Indiana.
13	Sulfur (Frasch-process)	Texas, Louisiana	Rank same as for quantity.
77	Sulfur ore for direct agricultural use	Nevada, California, Wyoming	Do.
28	Talc, pyrophyllite and ground soapstone	New York, California, North Carolina, Vermont	Do.
79	Tin (in ores and concentrates)	Colorado, North Carolina	Do.
	Titanium concentrates:		
33	Ilmenite	New York, Florida, Virginia, North Carolina	Do.
63	Rutile	Florida	Do.
57	Tripoli	Illinois, Missouri, Pennsylvania	Missouri, Illinois, Pennsylvania.
23	Tungsten concentrates	California, Nevada, North Carolina, Idaho	Rank same as for quantity.
47	Vermiculite	Montana, South Carolina, North Carolina, Wyoming	Do.
81	Wollastonite	New York	Do.
10	Zinc (in ores, etc.)	Montana, Idaho, New Jersey, Colorado	Do.
54	Zirconium concentrates	Florida	Do.

TABLE 4.—Value of mineral production in continental United States, 1948–51, by States, in thousands of dollars, and principal minerals produced in 1951

State	1948	1949	1950	1951			
				Value	Rank	Percent of U. S. total	Principal minerals in order of value
Alabama	183,797	143,905	158,975	164,279	20	1.22	Coal, iron ore, cement, stone.
Arizona	200,382	181,094	207,406	243,887	15	1.80	Copper, zinc, lead, silver.
Arkansas	122,089	109,523	118,642	118,693	24	.88	Petroleum, bauxite, coal, natural-gas liquids.
California	1,146,410	1,075,612	1,056,047	1,209,428	3	8.94	Petroleum, natural gas, natural-gas liquids, cement.
Colorado	128,861	[1] 139,873	[1] 154,898	179,434	18	1.33	Petroleum, molybdenum, coal, zinc.
Connecticut	4,484	4,887	5,675	6,299	45	.05	Stone, sand and gravel, lime, clays.
Delaware	403	335	522	644	48	(2)	Sand and gravel, stone, clays.
District of Columbia	64	63	60	82	49	(2)	Clays.
Florida	53,654	55,018	67,717	78,548	28	.58	Phosphate rock, stone, cement, sand and gravel
Georgia	36,103	35,508	44,157	48,509	32	.36	Clays, stone, cement, iron ore.
Idaho	79,128	64,292	79,077	82,793	27	.61	Zinc, lead, silver, sand and gravel.
Illinois	521,038	[1] 449,893	488,144	489,933	7	3.62	Coal, petroleum, stone, cement.
Indiana	161,950	141,025	166,632	174,389	19	1.29	Coal, petroleum, cement, stone.
Iowa	35,955	37,458	41,773	47,706	34	.35	Cement, stone, coal, sand and gravel.
Kansas	361,160	337,162	368,614	400,087	10	2.96	Petroleum, natural gas, cement, zinc.
Kentucky	504,080	372,229	459,956	442,264	8	3.27	Coal, petroleum, natural gas, stone.
Louisiana	604,198	631,813	693,607	787,678	5	5.82	Petroleum, natural-gas liquids, natural gas, sulfur.
Maine	8,094	6,742	7,461	8,516	44	.06	Cement, stone, sand and gravel, slate.
Maryland	25,002	20,461	22,725	26,027	38	.19	Sand and gravel, stone, cement, coal.
Massachusetts	12,583	12,449	16,014	16,951	41	.13	Stone, sand and gravel, lime, clays.
Michigan	202,885	201,260	[1] 229,941	257,939	12	1.91	Iron ore, petroleum, cement, salt.
Minnesota	267,248	257,540	331,567	433,098	9	3.20	Iron ore, sand and gravel, stone, manganiferous ore
Mississippi	119,317	103,711	102,945	103,030	25	.76	Petroleum, natural gas, clays, natural-gas liquids.
Missouri	108,291	111,293	113,191	135,246	22	1.00	Lead, cement, stone, coal.
Montana	103,841	98,070	103,389	126,166	23	.93	Zinc, copper, petroleum, lead.
Nebraska	8,385	10,102	14,022	18,469	40	.14	Cement, petroleum, sand and gravel, stone.
Nevada	42,503	[1] 37,373	48,499	57,626	30	.43	Copper, zinc, tungsten, gold.
New Hampshire	1,331	[1] 1,389	1,711	1,296	46	.01	Sand and gravel, feldspar, stone, clays.
New Jersey	44,388	38,584	46,391	59,024	29	.44	Zinc, stone, sand and gravel, iron ore.
New Mexico	220,080	198,825	210,294	256,304	14	1.90	Petroleum, potassium salts, copper, zinc.

Digitized by Google

New York	143,623	138,493	156,529	188,256	17	1.39	Iron ore, cement, stone, sand and gravel.
North Carolina	18,231	19,755	[1] 26,338	29,648	36	.22	Stone, sand and gravel, tungsten, clays.
North Dakota	8,478	8,818	9,614	10,246	43	.08	Coal (lignite), sand and gravel, stone, petroleum.
Ohio	284,816	242,080	274,572	302,013	11	2.24	Coal, stone, cement, lime.
Oklahoma	506,846	484,264	527,095	607,485	6	4.49	Petroleum, natural-gas liquids, natural gas, zinc.
Oregon	23,923	21,845	21,542	28,401	37	.21	Stone, sand and gravel, cement, diatomite.
Pennsylvania	1,386,960	1,035,970	1,186,212	1,289,226	2	9.53	Coal, cement, petroleum, stone.
Rhode Island	1,450	929	1,425	1,278	47	.01	Stone, sand and gravel, graphite.
South Carolina	8,885	9,026	11,394	11,284	42	.08	Clays, stone, cement, vermiculite.
South Dakota	24,327	[1] 26,746	32,716	29,658	35	.22	Gold, stone, clays, sand and gravel.
Tennessee	93,599	77,333	89,694	99,854	26	.74	Coal, cement, stone, zinc.
Texas	2,830,283	2,379,793	2,673,950	3,268,555	1	24.17	Petroleum, natural-gas liquids, natural gas, sulfur.
Utah	204,459	177,825	229,956	257,144	13	1.90	Copper, coal, lead, gold.
Vermont	15,999	17,384	18,563	18,535	39	.14	Stone, slate, asbestos, copper.
Virginia	143,333	116,408	137,806	161,251	21	1.19	Coal, stone, cement, sand and gravel.
Washington	48,928	40,863	49,055	54,552	31	.40	Cement, sand and gravel, zinc, coal.
West Virginia	1,012,402	718,119	829,624	941,723	4	6.96	Coal, natural gas, petroleum, natural-gas liquids.
Wisconsin	37,108	35,878	41,693	48,348	33	.36	Stone, sand and gravel, iron ore, zinc.
Wyoming	172,004	150,998	177,577	201,834	16	1.49	Petroleum, coal, clays, natural gas.
Total	12,273,000	10,580,000	11,855,000	13,524,000	--------	100.00	Petroleum, coal, iron ore, cement.

[1] Revised figure.
[2] Less than 0.005 percent.

[1] Excludes puzzolan cement, value for which is included with "Undistributed."
[2] Value included with "Undistributed."
[3] Less than $500.
[4] Final figure. Supersedes preliminary figure given in commodity chapter.
[5] Less than 0.5 ton.
[6] Sales in 1948 included with 1949.
[7] "Commercial." Value of "Noncommercial" included with "Undistributed."
[8] Excludes certain stone, value for which is included with "Undistributed."
[9] Figure withheld to avoid disclosure of individual company operations.
[10] Revised figure.
[11] Except clays sold or used for cement.
[12] Less than 500 troy ounces.
[13] Excludes natural cement, value for which is included with "Undistributed."
[14] Columbite and tantalite production not differentiated; value included with "Undistributed."
[15] Weight not recorded.
[16] "Noncommercial." Value of "Commercial" included with "Undistributed."
[17] Value reported for zinc in New Jersey is estimated smelting value of recoverable zinc content of ore after freight, haulage, smelting, and manufacturing charges are added.
[18] Less than 500 barrels.
[19] Quantity not available.

[1] The grouping of commodities is based upon the Standard International Trade Classification (United Nations) and a tentative conversion by the Bureau of the Census of United States import and export classifications to SITC categories. Data were compiled by the Office of Chief Economist, Bureau of Mines, from copies of unpublished tabulations on the foregoing basis supplied to the United Nations by the Bureau of the Census. As could be expected, individual commodities and groupings shown or omitted will not in all cases be in accordance with usual Bureau of Mines practice as followed in individual commodity chapters of this Minerals Yearbook. In some few cases, values for the same commodity will differ from those in the corresponding chapter because of reclassifications, exclusions or other reasons usually explained by footnotes in the chapter.

[2] Includes items entered for direct consumption, items withdrawn from bonded warehouse for consumption, and ores, etc., smelted and refined under bond at the time the refined product is withdrawn either for domestic consumption or for export.

[3] Includes both products mined in the United States and foreign mineral products which have been smelted, refined, manufactured, or otherwise processed in the United States.

[4] Does not duplicate items included in 672-01.

[5] Less than $500.

[6] Exclusive of silver and gold.

[7] Including natural gasoline and unfinished oils for further refining.

[8] This figure is about $4 million too low because of unrecorded omissions of certain classes of aviation gasoline.

[9] Pitch resin petroleum, asphalt, petroleum coke. Also includes miscellaneous byproducts of coal, lignite, petroleum, and oil shale, except chemicals.

[10] Includes no gypsum products.

[11] Builtup mica products and articles made from sheet mica and builtup mica.

[12] Includes lighting carbons, electrodes, carbon brushes, and brush stock and battery carbons.

[13] Includes retorts, crucibles, mufflers, nozzles, plugs, supports, tubes, pipes, sheets and rods.

[14] Does not include platinum allied metals and alloys.

[15] Does not duplicate items included in 272-07.

[16] Included in "cut but not set, other."

[17] Includes alloys.

[18] Not separately recorded. Included in 283-01 (*see* Crude metallic minerals).

Employment and Injuries in the Mineral Industries[1]

By Seth T. Reese

GENERAL SUMMARY

THE AVERAGE number of men working daily in the mineral industries declined 2 percent in 1951 to 702,715. However, mineral plants were active an average of 239 days, 18 more than in 1950. This increased plant activity produced a 5-percent gain in the total man-hours worked. The average employee in the industries in 1951 worked a 7.90-hour shift, unchanged from 1950. The average hours of work during the year at mineral plants was 1,889, or 139 more than during 1950. Increased average plant activity in 1951 was noted in each of the major branches of the mineral industries, except at metallurgical plants. The greatest increase in operations was in the coal industry, in which work stoppages were not as extensive as in 1950. There were slight increases in operating activity at metal and nonmetal mines, quarries, and coke plants.

The injury experience at operations in the mineral industries improved only slightly in 1951. A total of 974 fatalities, 131 more than in 1950, occurred at a frequency of 0.73 per million man-hour of exposure. This represented a 9-percent increase from the corresponding rate in 1950. An estimated total of 54,538 nonfatal injuries occurred at the rate of 41.09 per million man-hours in 1951. Although this was an increase of over 2 percent in number of injuries, the rate of occurrence was nearly 3 percent lower than the corresponding rate in 1950, due entirely to the 5-percent gain in total man-hours of worktime.

There were 5 major disasters (a single accident in which 5 or more men are killed) in the mineral industries during 1951. Four of them occurred at bituminous-coal mines and caused a loss of 152 men. The other disaster, at an anthracite mine, killed 5 men. This record of disasters was the worst since 1947 when, in 6 disasters, 179 men lost their lives. In 1951, 119 men were killed by an explosion in the Orient No. 2 mine at West Frankfort, Ill. This loss of life was larger than in the Centralia-mine explosion in the same State in 1947 and the most severe disaster since 1928, when an explosion at the Mather mine in western Pennsylvania killed 195 men.

Fatality experience improved at nonmetal mines, coke plants, and metallurgical plants. Not only were there substantial improvements in the rates, but also the number of fatalities was reduced appreciably. However, in the coal industry, at metal mines, and at quarries more men were killed and the rates of injury occurrence were higher in 1951 than in 1950.

The rates of nonfatal-injury frequency were better than in 1950 in the coal and metal industries, although the number of lost-time injuries increased. This was possible because of the increased man-

[1] Data on the oil and gas industries are treated separately in the last section of this chapter. Data on sand and gravel and clay industries and on iron-smelting and steel industries are excluded from this chapter.

Digitized by Google

hours of worktime. At coke plants the number of injuries and the rate of frequency were less than in the previous year. At nonmetal mines, quarries, and metallurgical plants increases in number of injuries were accompanied by increases in rates of frequency.

Work Stoppages.—According to the Bureau of Labor Statistics there were 650 work stoppages in the mineral industries during 1951. Of these, 549 at bituminous-coal mines caused a loss of 887,000 man-days, 30 at anthracite mines resulted in a loss of 81,000 man-days, 24 at nonmetal mines and quarries caused a loss of 53,000 man-days, and 23 at metal mines caused a loss of 269,000 man-days. The 12 stoppages at cement mills, 8 at petroleum refineries, and 4 at coke plants caused an additional loss of 60,000 man-days. Although there were 119 more work stoppages among the mineral industries in 1951 than in 1950 they lasted a shorter time. The total of 1,350,000 man-days of work idleness in the minerals industries in 1951 was one-eighth of the total loss caused by work stoppages in 1950.

Average Earnings.—Average hourly and weekly earnings increased in each of the mineral industries for which data are published by the Bureau of Labor Statistics, as shown in table 2.

Labor Turn-Over.—Labor turn-over in the mineral industries for which data were published by the Bureau of Labor Statistics followed the same pattern in 1951 as in 1950, with the highest in metal mining and the lowest in petroleum refining. The separation rates were lower than the accession rates in 1951 in each of the mineral industries, except anthracite and bituminous-coal mining. The accession rates in the anthracite industry and the separation rates in the petroleum-refining industry remained unchanged during 1950 and 1951.

NATIONAL SAFETY COMPETITION

Safety competitions, sponsored and conducted annually by the Bureau of Mines, have proved effective in promoting accident-prevention work in the minerals industry of the country. An encouraging number of the 751 mineral plants enrolled in the National Safety Competition and the National Sand and Gravel Safety Competition made outstanding safety records in 1951. Of the operations enrolled in these 2 contests, 228 (30 percent) attained injury-free records. Aggregate worktime at these injury-free plants was almost 22 million man-hours. In addition, the Bureau of Mines conducts four other competitions sponsored annually by National associations connected with the minerals industry. These associations are: National Sand and Gravel, National Lime, National Slag, and National Crushed Stone. In these contests of the 256 plants enrolled in 1951, 82 (32 percent) had injury-free records during an aggregate worktime of about 7 million man-hours.

Trophy awards for the best safety records in each of the six groups of the National Safety Competition were made to the following:

Anthracite Underground Mines.—No. 5 Hill mine, Ploskonka Coal Co., Archbald, Pa.

Bituminous-Coal Underground Mines.—Reliance No. 7 mine, Union Pacific Coal Co., Reliance, Wyo.

Metal Underground Mines.—Soudan underground mines, Oliver Iron Division of United States Steel Co., Soudan, Minn.

Nonmetal Underground Mines.—Retsof mine, International Salt Co., Inc., Retsof, N. Y.

Open-Pit Mines.—Mountain Iron open-pit mine, Oliver Iron Mining Division of United States Steel Co., Mountain Iron, Minn.

Quarries.—Port Inland quarry, Inland Lime & Stone Co., Gulliver, Mich.

[1] Preliminary figures based on an average of 80 percent coverage.
[2] Average number of men at work each day mine was active. Because absenteeism and labor turnover are taken into consideration, this number is lower than number of men available for work, as measured by a count of names on payroll.
[3] Average in which operating time of each mine is weighted by average number of workers in mine.
[4] Totals of man-days and man-hours are additions of rounded subtotals and may differ slightly from totals obtained before rounding.

[1] Number of stoppages beginning during each year and man-days of work lost from only these stoppages during the year.

[2] Monthly averages for production and related workers only; data cover both full- and part-time employees who worked during, or received pay for, the pay period ended nearest the 15th of the month.

[3] Monthly averages expressed as the number per 100 employees. Accessions are additions to the work force, whether new or rehired employees; separations are terminations of employment, including quits, discharges, lay-offs, and military and miscellaneous separations. Data for metal mining, cement, and petroleum refining for 1950 and 1951 are not comparable with preceding years, owing to changes in industry classification by the Department of Labor.

[4] An 11-month average owing to strike during February.

[5] Figure not available.

[6] Revised figure.

[1] Includes preliminary data except coke, which is final.

COAL MINES

Fatality experience at coal mines during 1951 was appreciably worse than that in 1950, and the rate of occurrence of fatalities was higher than in any year since 1948. The increase in the fatality record resulted entirely from the large number of men killed in mine disasters. However, nonfatal-injury experience continued to improve, and the rate of occurrence of nonfatal injuries in 1951 was lower than in any year since 1930, when these data became available. A total of 785 men was killed in the coal-mining industry during 1951, at a frequency rate of 1.06 per million man-hours. The rate of occurrence was 18 percent higher than the record low rate of 0.90 in 1950. Similarly, on a tonnage basis the fatality rate advanced to 1.36 per million tons mined in 1951 or appreciably above that of 1.14 in 1950. Failure to control the explosion hazard through safe ventilation practices, effective rock-dust controls, and adequate rock dusting ruined what could have been a relatively favorable fatality record. In 1951, 162 or 21 percent of the total fatalities occurred in major and local explosions of gas or dust.

Conversely to the fatality record, the nonfatal-injury experience in 1951 was a 3-percent improvement over the former low record in 1950. This improvement in 1951 continued the persistent year-to-year betterment in safety that has prevailed since 1946. Alhough the number of nonfatal injuries increased 376 to a total of 37,640 in 1951, the rate of occurrence of these injuries was 50.70 per million man-hours of exposure—a slight improvement over the corresponding rate of 52.38 in 1950. The lower rate in 1951 resulted from the greater total time of exposure of the men to the hazards of mining than in 1950. The

Digitized by Google

average number of men working daily decreased in 1951, but man-days and man-hours of work were appreciably higher than in 1950 owing to an increase in worktime. Coal mines were active an average of 210 days (21 more than in 1950). The average length of shift was 7.78 hours, and the total worktime per man-year was 1,637 hours (165 hours more than in 1950).

Bituminous-Coal Mines.—The average number of men working daily in bituminous-coal mines decreased to 384,300, a 6-percent reduction compared with the daily working force in 1950. Results of a monthly canvass of bituminous-coal operations showed a regular month-to-month downtrend in employment from 404,700 in January to 373,400 in December. Although the labor force was not as great as in 1950, man-hours of worktime rose to 635.4 million, an increase of 7 percent over the total worktime in 1950. The increased worktime resulted from a 14-percent increase in the average number of days operations were active. The average miner in 1951 worked a 7.86-hour shift for 210 active days compared with a shift of 7.88 hours for 185 days in 1950. The average worker at bituminous-coal mines had a total work-year of 1,653 hours (197 hours more than in 1950). The decrease in the average number of men to 384,300 in 1951 from 408,623 in 1950 was not reflected in the production at bituminous-coal operations. The production increased 3 percent to a total of 533,665,000 tons.

The fatality experience at bituminous-coal mines in 1951 was less favorable than in 1950. In all, 685 men were killed at bituminous-coal mines in 1951, an increase of 135 over the 1950 total of 550. These fatalities occurred at rates of 1.08 per million man-hours and 1.28 per million tons of coal mined, both well above the corresponding rates of 0.92 and 1.06 for the industry in 1950. Although both the number and frequency rates of fatalities were appreciably higher than in 1950, they were better than in any year, except 1949 and 1950, since collection of complete fatality statistics was begun in 1910.

The 685 fatalities were distributed among the following types of operations in 1951: 621 in underground workings, 35 on the surface, and 29 in stripping operations. In underground workings, falls of roof and face caused 312 deaths, explosions (major and local) of gas or dust 153, haulage 103, machinery and electricity 19 each, explosives 7, and miscellaneous 8.

Nonfatal-injury experience was also less favorable at bituminous-coal mines in 1951 than in 1950. The 30,525 disabling injuries for the year represented an 8-percent increase over the previous year's total of 28,390 injuries. The nonfatal-injury rates in 1951 were 48.04 per million man-hours and 57.20 per million tons, both rates less favorable than the respective rates of 47.73 and 54.82 in 1950.

Anthracite Mines.—The average number of men working daily at anthracite operations decreased from 74,616 men in 1950 to 69,300 in 1951, and worktime declined 8 percent to 106.9 million man-hours. The average employee in 1951 worked a 7.35-hour shift and performed 1,543 hours of work (19 hours less than in 1950).

The fatality experience at anthracite mines was less favorable in 1951 than in 1950. In all, 100 men lost their lives in the anthracite industry, or 7 more than in the previous year. These fatalities occurred at frequency rates of 0.94 per million man-hours and 2.34 per million tons. Comparable data for 1950 were 93 men killed at frequency rates of 0.80 per million man-hours and 2.09 per million tons. The

302512—54——7

Digitized by Google

100 fatalities at anthracite mines occurred as follows: 89 in underground workings, 8 on the surface, and 3 in stripping operations. Falls of roof and face killed 51 men (57 percent of the total) in underground workings in 1951. In 1950 this type of accident resulted in 58 fatalities (74 percent of the underground total). Haulage accidents were responsible for 10 more fatalities in 1951 than in 1950, and an explosion of gas at an anthracite mine, resulting in the death of 5 men, increased the toll from this type of accident to 9 or 4 more than in 1950. This disaster in 1951 was the first one in the anthracite industry since 1947. The disaster record of this industry has been good in recent years, as 10 of the past 13 years have been disaster-free.

There were 7,115 lost-time injuries in the industry in 1951 (20 percent less than in 1950, when 8,874 disabling injuries were reported). The fewer number of injuries in 1951 resulted in a sharp reduction in the frequency rates—66.55 per million man-hours compared with 76.14 for 1950—continuing the downward trend that has persisted each year since 1946. The frequency rate per million tons of coal mined in 1951 was 166.74, and in 1950 it was 199.75.

TABLE 4.—Employment and injury experience at coal mines in the United States, 1947–51

[1] Includes lignite.

METAL MINES

Injury experience at metal mines in 1951 improved slightly. The total injury-frequency rate of 43.43 injuries (fatal and nonfatal) per million man-hours was 4 percent lower than the comparable rate of 45.31 for 1950. However, this improvement was due entirely to a lower nonfatal rate, for the fatality experience at metal mines in 1951 was slightly higher than in the previous year.

The daily average number of men working increased 6 percent to a total of 72,600; these men worked almost 162 million hours, or 9 percent more than in 1950.

Digitized by Google

Iron Mines.—The average number of men at work daily at iron mines increased to 30,200 in 1951. The mines were worked an average of 279 days, compared with 268 days in 1950. Each worker averaged 2,239 hours (93 more than during 1950). Total man-hours rose to 67.6 million—a 14-percent increase over 1950. The number of fatalities and nonfatal injuries increased to 34 and 1,275, respectively, from 23 and 1,126 in 1950. The fatality frequency rate of 0.50 per million man-hours was less favorable than the 0.39 rate for 1950; however, the nonfatal-injury frequency rate of 18.85 was slightly better than the corresponding rate in 1950.

TABLE 5.—Employment and injury experience at metal mines in the United States, 1947–51, by industry group

Industry and year	Men working daily	Average active mine-days	Man-days worked	Man-hours worked	Number of injuries		Injury rates per million man-hours	
					Fatal	Non-fatal	Fatal	Non-fatal
Iron mines:

Copper Mines.—The number of men working daily at copper mines rose in 1951 to 16,100. Total man-hours at all copper mines were a little more than 5 percent greater than in 1950. In 1951 the average manshift was 8.00 hours, and the average workyear per man was 2,439 hours or virtually equal to the previous year's average figure. The number of days worked was identical—305. The safety record at copper mines in 1951 was less favorable than in 1950. The 22 fatalities in 1951 (5 more than in 1950) occurred at a rate of 0.56 per million man-hours, or at a 22 percent higher rate than in the previous year. Nonfatal injuries totaled 1,305 for the year, at a frequency of 33.24 injuries per million man-hours. The corresponding rate in 1950 was 31.49.

Lead-Zinc Mines.—The daily average number of workers in 1951 at lead-zinc operations (15,000) was 7 percent greater than in 1950. Similarly, total man-hours worked at these plants were higher for the year, and the average number of days worked increased 15. Each worker averaged a shift of 7.97 hours and accumulated 2,166 hours for the year (109 more than in 1950). Fatality experience at lead-zinc mines in 1951 was considerably more favorable than in 1950. Likewise, the nonfatal injury rate improved, but to a smaller extent. The 15 fatalities (13 less than in 1950) occurred at a frequency rate of 0.46 per million man-hours and the 2,685 lost-time injuries at a rate of 82.64. The respective rates for the previous year were 0.97 and 83.49.

Gold-Silver Lode Mines.—The average number of men working at gold-silver lode mines totaled 4,400, a loss of 14 percent compared with 1950. Three fewer days were worked in 1951, and the total of 8.9 million man-hours of worktime was 14 percent lower than that during 1950. The average worker had a 7.78-hour shift and accumulated a total of 2,011 hours for the year (9 hours less than in 1950). Fatality experience at gold-silver lode mines was considerably worse than in 1950, a year when the record at these mines was not favorable. The 16 fatalities, compared with 10 in 1950, caused a fatality rate of 1.81 per million man-hours. Nonfatal injuries totaled 885, a decrease of 385 under the 1950 total number. They occurred at a rate of 100.00 injuries per million man-hours, a considerable improvement over the rate of 122.96 for 1950 but still the highest in the mineral industries in 1951.

Gold Placer Mines.—In 1951, an average of 3,500 men was working daily at gold placers—about the same as in 1950. Total man-hours of worktime decreased slightly because these operations working 8 days less than in 1950. The average worker increased his hours per day of work to 8.11 but had 46 fewer hours in total for the year's work. The injury experience at gold placer operations was less favorable in 1951 than in 1950. The 2 deaths during the year occurred at a rate of 0.34 per million man-hours. No one was killed in 1950. The number of nonfatal injuries (185 or 1 more than the previous year) occurred at a rate of 31.09 per million man-hours. The corresponding rate for 1950 was 30.48.

Digitized by Google

Miscellaneous Metal Mines.—The average daily number of workers, (3,400) was 30 percent greater than in 1950 at mines in this group. This division included plants producing antimony, bauxite, chromite, cobalt, manganese, mercury, molybdenum, pyrite, titanium, tungsten, and vanadium-uranium. The man-hours of worktime also increased 32 percent to a total of 7.6 million, and the average employee worked 2,235 hours during the year (30 more than during 1950). The safety record at mines in this group showed no improvement in 1951 as compared with 1950. Although the fatality frequency rate was somewhat lower, the nonfatal rate increased. The combined rate (fatal and nonfatal) in 1951 was 79.21, while in 1950 it was 78.01.

NONMETAL MINES (EXCEPT STONE QUARRIES)

This group includes barite, feldspar, fluorspar, gypsum, magnesite, mica, phosphate rock, rock salt, sulfur, and miscellaneous nonmetallic mineral operations. The average of 12,800 men at work daily was slightly higher than the total for 1950. These mines worked an average of 294 days, 1 more than in 1950, for a total of 30.2 million man-hours, 6 percent more than in 1950. The average employee did not work as many hours during the year, as his workday was 0.07 hour shorter than in 1950. The overall injury experience at nonmetal operations was not as good as in 1950. The 15 fatalities (4 less than the previous year's total) occurred at the rate of 0.50 per million man-hours. This betterment was offset by increased nonfatal injuries, which occurred at a rate of 45.91 per million man-hours. The corresponding rate for 1950 was 43.51.

TABLE 6.—Employment and injury experience at nonmetal mines (except stone quarries) in the United States, 1947–51 [1]

Year	Men working daily	Average active mine-days	Man-days worked	Man-hours worked	Number of injuries		Injury rates per million man-hours	
					Fatal	Non-fatal	Fatal	Non-fatal
1947	12,176	292	3,554,901	28,809,150	12	1,308	0.42	45.40
1948	11,950	287	3,432,304	27,784,119	15	1,176	.54	42.33

1950	11,977	293	3,512,094	28,455,936	19	1,238	.67	43.51
1951 (preliminary)	12,800	294	3,757,000	30,170,000	15	1,385	.50	45.91

[1] Includes barite, feldspar, fluorspar, gypsum, magnesite, mica, phosphate rock, rock salt, sulfur, and miscellaneous nonmetallic-mineral mines.

STONE QUARRIES

Injury experience in the quarrying industries in 1951 was less favorable, and the rates of occurrence of both fatal and nonfatal injuries increased over 1950. However, these increases were slight. The 1951 combined injury rate (fatal and nonfatal) per million man-hours was 25.50 as against 25.40 for the preceding year. Operating activity in each of the quarrying industries increased, and man-hours of worktime rose 5 percent over 1950. The average number of men working daily increased from 85,730 to 88,200—almost 3 percent. The average length of shift (8.17 hours) and the average number of hours worked per man (2,254) were slightly higher than in 1950.

[1] Includes burning or calcining and other mill operations.

Cement Mills and Associated Quarries.—The average number of men working daily at cement mills and associated quarries during 1951 was virtually identical with that in 1950. The 29,000 men worked an average of 327 days. The average worker had a shift of 7.98 hours and a workyear of 2,610 man-hours. Total man-hours of worktime in the industry increased by 1.9 million. The injury experience at cement operations improved in 1951. Decreases in the number of injuries, coupled with an increase in man-hours of worktime, were reflected in substantial decreases in the fatal and nonfatal frequency rates of 22 percent and 9 percent, respectively.

Digitized by Google

Limestone Quarries.—An average of 29,500 men worked daily at limestone quarries in 1951, a gain of almost 1,000 over 1950. These quarries worked 236 days during the year and reported 8.56 hours as an average length of shift. The total man-hours of worktime increased 8 percent to 59.6 million man-hours. At limestone operations the rates of frequency of both fatal and nonfatal injuries increased in 1951 over 1950, despite the 8-percent increase in man-hours of worktime.

Lime Plants.—The average number of men working at lime plants and associated quarries increased 9 percent to 9,600 in 1951. The average length of shift of 7.76 and the average number of 2,298 hours worked per man during the year were lower than in 1950. As the lime industry had 8 fatalities during the year, compared with 6 in 1950, the fatality rate rose to 0.36 per million man-hours. However, the nonfatal rate fell to 27.43 owing to an 11-percent decrease in the number of lost-time injuries.

Marble Quarries.—The total of 2,700 men working daily at marble operations was a gain of 100 over 1950. This increase in men working, together with a longer workyear for each worker, resulted in a higher total man-hours of worktime for the industry. There were no fatalities at marble operations in 1951, but 180 lost-time injuries were reported (12 more than in 1950). However, due to the increased worktime, the nonfatal injury rate improved slightly over the previous year.

Granite Quarries.—In 1951 the average number of men working at granite quarries rose to 7,600, and the number of days worked averaged 259 (10 more than in the preceding year). Total worktime was 4 percent higher in 1950. In 1951 the average granite employee had a shift of 8.08 hours and a workyear of 2,093 hours, 34 more than in 1950. Fatality experience at granite operations was considerably less favorable than in 1950. The 7 fatalities occurred at the rate of 0.44 per million man-hours, which was higher than the 0.13 rate for the preceding year. Although there were 13 more nonfatal injuries at granite quarries, the nonfatal rate of 37.71 was slightly less than the previous year's rate, due to the 4-percent increase in the total man-hours worked.

Traprock Quarries.—On the average, at traprock quarries in 1951, a total of 3,200 men, worked 238 days—13 more than in 1950. The aggregate of 6.3 million man-hours of work at these quarries was 8 percent higher than the corresponding total for 1950. The average shift was 8.23 hours, and each worker averaged a workyear of 1,963 hours (62 hours more than in 1950). From an overall standpoint, the safety record at traprock quarries was less favorable in 1951 than in 1950. The 2 fatalities at these operations occurred at a rate of 0.32 per million man-hours and the 400 nonfatal injuries at a rate of 63.69. The combined rate (fatal and nonfatal) of 64.01 was 27 percent higher than the same rate for 1950.

Slate Quarries.—At slate quarries the average number of men working increased to 2,200, while the average number of days worked rose to 272, 4 more than in 1950. Worktime increased 8 percent to a total of 5.0 million man-hours. On the average, each worker had a 2,282-hour workyear and an 8.38-hour shift. There were no fatalities at slate operations in 1951, but there were 220 nonfatal injuries (17 more than in 1950). The nonfatal injury rate of 43.82 per

Digitized by Google

million man-hours was virtually identical to the 1950 rate. The 8-percent increase in man-hours of worktime was responsible for keeping this rate in line with that of the previous year.

Sandstone Quarries.—The average number of men working daily at sandstone quarries increased to 4,400, who averaged 236 working days during the year, 6 less than in 1950. The aggregate of 8.5 million man-hours was slightly higher than the total for 1950. The average employee worked an 8.18-hour shift and had a 1,927-hour workyear (80 less than in 1950). Injury experience at sandstone operations was slightly better in 1951 than in 1950. The 2 fatalities in 1951 occurred at a frequency rate of 0.24 or double that of the previous year; but the decrease in the nonfatal frequency rate was sufficient to reduce the 1951 combined rate below that of 1950.

COKE PLANTS

The average number of men working at coke plants rose to 25,715, who averaged 344 active working days during the year. Man-hours of worktime at coke plants increased 7 percent over that in 1950 to slightly over 70 million. Fatality experience improved sharply; the rate of deaths per million man-hours was 33 percent lower than the 1950 rate. The nonfatal injury frequency rate dropped from 11.84 in 1950 to 10.94 in 1951. The average employee at coke plants worked a 7.95-hour shift to accumulate a workyear of 2,730 hours, 25 more than in 1950.

Byproduct-Coke Plants.—The number of men working at byproduct-coke plants increased to a daily average of 22,058, while active days averaged 363. Worktime totaled 64.1 million hours, 6 percent higher than in 1950. The average worker had an 8.01-hour shift and a 2,906-man-hour workyear. The 9 fatalities in 1951 were 4 less than in 1950, and these occurred at a rate of 0.14 per million man-hours, or 33 percent under the previous year's rate. The total of 533 nonfatal injuries in 1951 had a frequency of 8.31 compared with 8.52 in 1950.

TABLE 8.—Employment and injury experience at coke plants in the United States, 1947–51

Type and year	Men working daily	Average active plant-days	Man-days worked	Man-hours worked	Number of injuries		Injury rates per million man-hours	
					Fatal	Non-fatal	Fatal	Non-fatal
Byproduct ovens:

Beehive-Coke Plants.—The average number of men working daily at beehive plants advanced to 3,657 in 1951, and the plants were active 18 days more than in 1950, increasing the total man-hours of work to almost 16 percent above the preceding year. In 1951 the average employee had a 7.3-hour shift and worked 1,665 hours (118 more than in 1950). The lone fatality in 1951 occurred at a rate of 0.16 per million man-hours, slightly lower than the rate in 1950. The total of 235 nonfatal injuries had a frequency of 38.60 per million man-hours or a decline of 23 percent under the 1950 rate.

METALLURGICAL PLANTS

Injury experience at metallurgical plants was slightly less favorable in 1951 than in 1950. Although the number of fatalities was reduced one-third, the number of nonfatal injuries increased almost 9 percent above that in 1950. The combined frequency rate of injuries (fatal and nonfatal) in 1951 was 22.69 and the corresponding rate in 1950 22.36. The average number of men working daily rose to 49,800, and the total worktime was 7 percent greater than in 1950.

Ore-Dressing Plants and Auxiliary Works.—Plants or mills in this group are those in which ores of all metals are processed by various methods of treatment. The average number of men working in all metal mills in 1951 increased 7 percent to a total of 16,000, owing to increases in each group. This increase, accompanied by an increase in hours per shift, resulted in a gain of almost 9 percent in man-hours of worktime. The average employee in 1951 worked an 8.08-hour shift and 2,361 hours during the year (33 more than in 1950). The overall injury experience at metal mills was slightly more favorable than in 1950. As there were 4 fewer fatalities, the rate dropped from 0.20 to 0.08, but this betterment was almost offset by 65 more nonfatal injuries. The frequency rate of lost-time injuries was just slightly better than in 1950 and resulted from the increase in man-hours of worktime. Fatality experience was improved in copper and iron mills, and, except in lead-zinc mills, the nonfatal injury experience was better in each group. At lead-zinc operations the frequency of disabling injuries increased from 31.29 to 38.75 per million man-hours in 1951.

Nonferrous Reduction Plants and Refineries.—This group of plants is engaged in the primary extraction of nonferrous metals from ores and concentrates and includes smelters, refineries, roasting, electrolytic, and all other nonferrous metal reducing or refining plants. Iron and steel plants are not included.

The average number of men working in each division of plants in this classification increased in 1951 except at lead plants, where the average was 1 percent lower than in 1950. For the group, the average number of men working increased 8 percent in 1951, but man-hours

Digitized by Google

of worktime were not increased in this proportion as 6 fewer days were worked. The average shift was 8.02 hours and the worktime per man-year 2,554 hours in 1951 (52 less than in 1950). The overall safety record at plants in this classification was less favorable than in 1950. There were 15 fewer fatalities, and the frequency rate of fatalities was a 70-percent improvement over the 1950 rate. However, the nonfatal injury rate rose from 21.92 to 22.65 in 1951. The poorest showing in safety was at miscellaneous metal smelters where the combined frequency rate of injuries (fatal and nonfatal) increased 30 percent. The greatest improvement was made in the lead group through a 16-percent reduction in rate of occurrence.

[1] Includes smelters, refineries, roasting, electrolytic, retort, and all other nonferrous metal reducing or refining plants.
[2] Includes mercury, antimony, tin, and magnesium plants.

OIL AND GAS INDUSTRIES

This chapter is the first on Employment and Injuries to give data on the oil and gas industries. However, data for these industries have not been combined with those for the group of extractive industries, designated as "the mineral industries," covered in other sections of this chapter and to which coverage was restricted in earlier chapters.

It is believed that the statistics given herein present a reasonably comprehensive picture of injury and employment experience in the oil and gas industries, because in the canvasses fairly adequate coverage has been obtained of medium- and small-size operating companies and of oil and gas contractors, and especially good coverage obtained of the large companies. It is hoped that in 1952 and subsequent years the coverage will be expanded, especially of the medium- and small-size companies. It is estimated that, exclusive of marketing and inland water transportation, for which coverages are least satisfactory, the data cover the greater part of the oil and gas industries.

The safety record of the oil and gas industries in the United States was less favorable in 1951 than in 1950. There were 142 fatalities compared with 109 the year before. The fatality rate of 0.12 per million man-hours was a 20-percent increase over the corresponding

Digitized by Google

rate for the preceding year. Nonfatal injuries increased from 13,500 in 1950 to 15,130 in 1951, and the rate of frequency increased from 12.48 to 13.18. The 6-percent increase in the man-hours of worktime in 1951 over 1950 did not offset the 12-percent increase in the total number of injuries. The average worker accumulated 2,129 hours during the year, 40 more than in 1950.

TABLE 11.—Employment and injury experience in the oil and gas industries in the United States, 1949–51, by department

Department and year	Average number of men working daily	Man-hours worked	Number of injuries		Injury rates per million man-hours	
			Fatal	Nonfatal	Fatal	Nonfatal
Exploration:						
1949	10,906	23,800,551	9	314	0.38	13.19
1950	10,188	22,036,726	1	258	.05	11.71

Fuels and Energy

By Orris C. Herfindahl and Herbert E. Striner

GENERAL SUMMARY

LONG-TERM trends in the growth and relative importance of primary fuels and energy continued in 1951. Petroleum and natural gas continued their relative growth at the expense of bituminous and anthracite. Water power as a source of electrical energy also fell relative to the other sources of energy.

The long-term movements in the production of primary fuels and energy are shown in table 1 and figure 1. Although bituminous coal surpassed its previous 1918 peak in several years during and after World War II, annual production since 1948 has been below the 1918 peak. Anthracite production has been declining steadily since its World War I peak. In contrast, crude petroleum and natural gas have in-

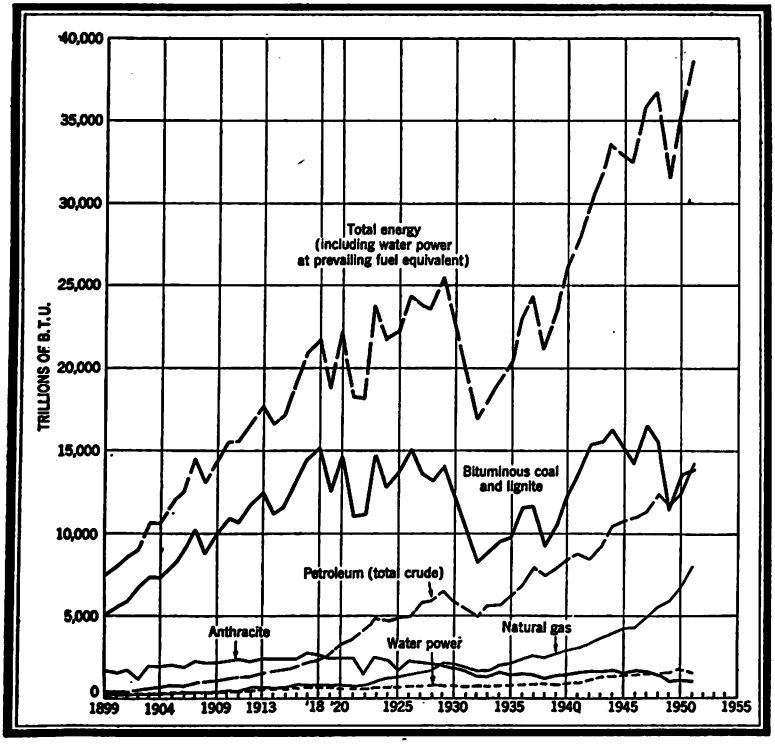

FIGURE 1.—Annual supply of energy from mineral fuels and water power in the United States, 1899–1951.

Digitized by Google

creased rather steadily over the whole period since the beginning of the century. Growth of natural-gas use has been especially rapid in recent years. The relative importance of these primary sources of energy is shown for selected years in table 2 and figure 2.

TABLE 1.—Annual supply of energy from primary mineral fuels and water power in the United States, 1900–51, in trillions of British thermal units [1]

Year	Pennsylvania anthracite	Bituminous coal and lignite	Total coal	Petroleum (crude)		Natural gas (marketed production)	Total petroleum and natural gas	Total mineral fuels	Water power [2]	Grand total
				Domestic production	Imports					
1900	1,457	5,563	7,020	369	---------	254	623	7,643	250	7,893
1905	1,973	8,255	10,228	781	---------	377	1,158	11,386	386	11,772
1910	2,146	10,928	13,074	1,215	3	547	1,765	14,839	539	15,378
1911	2,298	10,635	12,933	1,279	8	551	1,838	14,771	565	15,336

[1] The unit heat values employed are: Anthracite, 12,700 B. t. u. per pound; bituminous coal and lignite, 13,100 B. t. u. per pound; petroleum, 5,800,000 B. t. u. per barrel; natural gas, 1,075 B. t. u. per cubic foot. Water power includes installations owned by manufacturing plants and mines, as well as Government- and privately-owned public utilities. The fuel equivalent of water power is calculated from the kilowatt hours of power produced wherever available as it is true of all public-utility plants since 1919. Otherwise, the fuel equivalent is calculated from the reported horsepower of installed water wheels, assuming a capacity factor of 20 percent for factories and mines and of 40 percent for public utilities.

Not all imports of energy and energy materials are included. The most important omission is petroleum products other than crude oil. A small portion of mineral fuels (roughly 3 percent) is used for purposes other than the production of energy.

[2] Fuel equivalent calculated by assuming the average central-station practice for each of the years for which data are available.

[3] Preliminary figures.

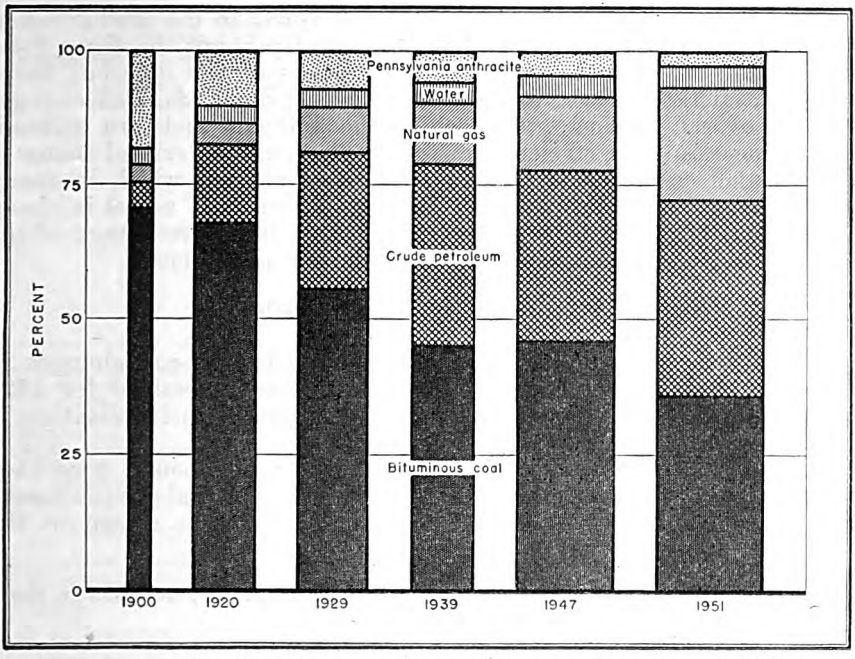

FIGURE 2.—Relative importance of primary fuels and energy, selected years, 1900–1951.

TABLE 2.—Relative importance of primary sources of energy in the United States, selected years from 1900 to 1951, in percent [1]

Fuel	1900	1920	1929	1939	1947	1950	1951
Bituminous coal	70.5	67.8	55.9	45.6	46.3	38.2	36.1
Crude petroleum	4.7	14.5	25.1	33.2	31.8	35.1	36.4
Natural gas	3.2	3.9	8.2	11.7	13.8	19.1	20.7
Water power	3.2	3.4	3.3	3.7	4.0	4.4	4.0
Pennsylvania anthracite	18.4	10.4	7.5	5.8	4.1	3.2	2.8
Total	100.0	100.0	100.0	100.0	100.0	100.0	100.0

[1] Percentages based upon figures given in table 1.

In interpreting the long-term movements in these data there are several important qualifications. First, the data are in terms of B. t. u. (British thermal unit) content; however, work delivered by these fuels will not be in proportion to their B. t. u. contents because the efficiency with which fuels are utilized varies among fuels and also among different uses of the same fuel. This means that the gross changes in B. t. u. content of production may not closely reflect changes in work performed. Also, it must be remembered that for many uses the user is interested in more than just the quantity of heat that he can get out of a fuel. In the case of household space heating, he is interested as well in "clean" heat. The vehicle owner is not only interested in the quantity of energy and cleanliness of the fuel but also the rapidity with which the energy output can be changed and in low-cost vehicle maintenance.

Digitized by Google

The factors behind the various rates of growth in the production of primary fuels and energy are numerous, but perhaps the three most important are changes in the relative prices of the different fuels, differential rates of growth in noncompeting demands, and changes in the overall efficiency with which the different fuels are utilized. In connection with efficiency of fuel utilization, the crucial factor is the overall cost (not fuel cost) per unit of output, which in many applications will mean cost per B. t. u. output. If a fuel is cheap enough, it may pay to use it even though a large percentage of the contained B. t. u.'s is "wasted" in producing usable heat.

USE OF FUELS AND ENERGY

Data are not available for tracing detailed short-run changes in the use of fuels and energy. Data have been assembled for 1929 and 1947, however, and show long-run changes in fuel utilization in considerable detail (*see* tables 3–9).

A small portion of the output of primary fuels—about 2 percent—is consumed in the production of these fuels. Natural-gas producers are the heaviest consumers of their own outputs as shown in the following table:

Self-consumption of fuels and energy as a percentage of production in the United States, 1947 [1]

[Based on B. t. u. content

Bituminous coal	0. 4
Anthracite	3. 3
Crude petroleum	1. 4
Natural gas [2]	10. 8
Hydroelectric power	--
Wood and waste	--
All	2. 3

[1] Percentage figures derived from Lyon, W. H., and Colby, D. S., Production, Consumption, and Use of Fuels and Electric Energy in the United States in 1929, 1939, and 1947: Bureau of Mines Rept. of Investigations 4805, 1951, p. 12.
[2] Does not include loss.

After accounting for self-consumption, the most important primary fuels and energy then available are bituminous coal, crude petroleum, and natural gas. The percentage distribution of the net outputs of primary fuels and energy industries, based on B. t. u. content, is shown in columns A of table 3 for 1929 and 1947.

To a large extent, primary fuels are changed in form before use by the non-energy-producing sectors of the economy. For example, crude oil is not consumed in these sectors until converted into more convenient forms. Much of the coal output is converted into electrical energy. These and other changes in the form of primary fuels in turn require energy, with the result that in 1947 only 86 percent of the net output of primary fuels and energy was available to the non-energy-producing sectors of the economy—not counting the fuel energy consumed in transporting fuel from sources to use locations.

Large changes have taken place in the forms in which fuels and primary energy are consumed outside the energy-producing industries (*see* table 3). In 1929, 61 percent of the B. t. u. consumption outside the energy-producing industries was made up of primary fuel or energy.

TABLE 3.—Primary and secondary fuels and energy available to non-energy-producing sectors of the United States economy, 1929 and 1947, by sources, in percent of total [1]

[Based on B. t. u. content with electric energy at central-station fuel-consumption rate]

Source of fuel and energy	1929 (A) Primary fuels and energy available after self-consumption	1929 (B) Primary and secondary fuels and energy available to nonenergy sectors	1947 (A) Primary fuels and energy available after self-consumption	1947 (B) Primary and secondary fuels and energy available to nonenergy sectors
Primary fuels and energy:				
Bituminous coal	55.4	44.2	45.6	30.3
Anthracite	7.0	7.2	3.9	3.4
Crude petroleum	23.9	[2]	31.2	
Natural gas	7.1	5.5	13.0	9.8
Hydroelectric energy:				
Utility	2.8		3.7	
Industrial	.4	.4	.2	.2
Wood and waste	3.4	3.8	2.4	2.7
Total primary	100.0	61.1	100.0	46.4
Secondary fuels and energy:				
Briquets and packaged fuel		0.1		0.2
Coking:				
Coke		6.8		5.9
Crude light oil		[2]		.1
Coal tar		.6		.4
Byproduct gas		1.2		1.0
Total coking		8.6		7.4
Other manufactured gas		0.7		0.6
Net blast-furnace gas		[2]		−0.1
Refinery products:				
Liquefied petroleum and refinery gases		[2]		0.6
Still gas				.1
Motor fuels		8.8		13.4
Distillate oils:				
Kerosine		.9		1.9
Diesel and other		9.6		5.4
Residual oil				8.1
Petroleum coke		.1		.1
Nonfuel products		1.3		2.0
Total refinery products		20.7		31.6
Utility electric energy		8.8		13.9
Grand total		100.0		100.0

[1] Columns A show primary fuels and energy available after accounting for imports, exports, self-consumption, and changes in stocks.

Columns B show all fuels and energy available to nonenergy sectors after accounting for imports, exports, consumption in primary and secondary energy-producing industries, and changes in stocks of energy-producing industries.

These distributions are derived from Lyon, W. H., and Colby, D. S., Production Consumption, and Use of Fuels and Electric Energy in the United States in 1929, 1939, and 1947: Bureau of Mines Rept. of Investigations 4805, 1951, 90 pp.

[2] Less than 0.05 percent.

By 1947 the movement to secondary forms of fuels and energy had reduced this to 46 percent. The main factors in this shift were the increased reliance on refinery products instead of coal and a relative increase in the use of electric energy. Refinery products provided 21 percent of the energy consumed by nonenergy sectors in 1929, but by 1947 this percentage had risen to 32. Bituminous coal provided 44 percent of the energy consumed by nonenergy sectors in

Digitized by Google

1929, but by 1947 this percentage had dropped to 30 percent of the total.

In contrast with the changes that have occurred in the relative importance of the types of fuels and energy used by the non-energy-producing sector, the distribution of energy use was much the same in both 1929 and 1947 in its broader aspects (*see* table 4). Manufacturing industries consumed about 28 percent of the total, with transportation and domestic-commercial taking about a third each. Within manufacturing, the iron and steel industry was by far the biggest user.

TABLE 4.—Fuels and energy used by nonenergy-producing industries in the United States, 1929 and 1947, by industries, in percent of total [1]

[Based on B. t. u. content, with electric energy at central station fuel-consumption rate]

Industry	1929	1947 [2]	Industry	1929	1947 [2]
Manufacturing industries:			Transportation industries:		
Iron and steel	10.3	9.3	Railroads	19.1	12.3
Chemicals and allied products	2.3	3.3	Highway	7.9	11.4
Stone, clay, and glass products	3.8	2.9	Pipeline and utility system usage and losses	2.2	2.9
Food and kindred products	2.5	2.3	Bunkers (foreign trade only)	3.0	2.5
Paper and allied products	1.8	2.1	Nonhighway:		
Nonferrous metals	.7	1.4	Civilian aviation	[3]	.2
Textile mill products	1.6	1.3	Other	1.2	1.4
Fabricated metal products	1.0	.6			
Other manufacturing industries	4.2	4.2	Total	33.4	30.7
Total	28.2	27.4	Army, Navy, and Coast Guard	.2	.9
Nonfuel mines and quarries	1.1	.7	Domestic and commercial	31.2	33.7
			Nonfuel use	2.9	4.3
			Miscellaneous	3.0	2.3
			Grand total	100.0	100.0

[1] Derived from source cited in footnote 1, table 3.
[2] Does not include a small quantity of liquefied gases and motor fuel used by manufacturing industries and mines and quarries (0.2 percent of total); also some liquefied petroleum gases used for highway and nonhighway transportation purposes (0.03 percent of total).
[3] Less than 0.05 percent.

Within these categories, however, were wide differences in rates of growth of energy use. Energy use in the chemicals, paper, and nonferrous metals industries grew relative to the total. Consumption of energy by railroads fell from 19 to 12 percent of the total from 1929 to 1947, but highway consumption (autos and trucks) rose from 8 to 11 percent.

Within industries, important shifts in the sources of fuel and energy took place from 1929 to 1947. Manufacturing as a whole shifted from bituminous coal to utility electric energy, distillate and residual oil, and natural gas (*see* table 5). The same relative movements took place in iron and steel. In chemicals and allied products, however, both coal and utility electric energy lost ground, especially to natural gas.

Similar shifts from solid fuels took place for railroads and domestic and commercial users. Railroads moved from coal to oils, whereas domestic and commercial users moved to natural gas, oil, and electric energy (*see* tables 6 and 7). Residential use and commercial space heating exhibited a great shift from solid fuels between 1935 and 1950 (*see* table 8). This movement continued from 1950 to 1951. In 1950 solid fuels provided 48 percent of these requirements, but only 43 percent in 1951.

[1] Based on B. t. u. content. Derived from source quoted in footnote 1, table 3.

In table 9, which shows a detailed breakdown of the percent distribution of selected fuels and energy to nonenergy-producing industries during 1929 and 1947, it is possible to compare the relative importance in 1947 of the markets for each of the fuels as against the relative importance of these same markets for the specific fuels in 1929.

FUEL EFFICIENCY

It has already been emphasized that a decisive criterion in selecting a fuel is its cost per unit of useful output. Cost per contained B. t. u. is not necessarily decisive and may be higher for the fuel actually selected than for those rejected. Cost per contained B. t. u. can be offset by more efficient utilization or cheaper burning equipment.

Digitized by Google

Cost of fuel per unit of useful output is not completely decisive because it is only a part of the total cost of obtained useful energy flow. The complete and relevant cost concept also must include labor and equipment costs. Even with these qualifications, however, fuel efficiency is an important element of overall energy cost. Because of this, data on fuel efficiency do serve as useful indicators of changes in energy cost, although the correspondence is not perfect.

Electric Generating Stations.—The long-run trends of fuel consumed per kilowatt hour in electric generating stations have been very similar for coal, oil, and gas. Data for 1920–51 are shown in table 10. The percentage by which fuel consumption declined per year was quite rapid in the early years following 1920. The rate of decline gradually slowed until the 1930's, when there were very few gains. Consumption of coal declined slightly during the late thirties and early forties.

TABLE 10.—Average consumption of coal, oil and gas per kilowatt-hour in electric generating stations in the United States, 1920–51 [1]

Year	Coal (pounds)	Oil (gallons)	Gas (thousand cubic feet)	Year	Coal (pounds)	Oil (gallons)	Gas (thousand cubic feet)
1920	3.0	0.254	36.9	1936	1.44	.118	17.1
1921	2.7	.220	31.0	1937	1.44	.118	17.1
1922	2.5	.209	31.2	1938	1.40	.113	17.1
1923	2.4	.195	29.3	1939	1.38	.099	16.3
1924	2.2	.182	26.3	1940	1.34	.111	16.5
1925	2.0	.164	23.9	1941	1.34	.112	16.8
1926	1.9	.157	22.9	1942	1.30	.114	16.7
1927	1.82	.153	21.5	1943	1.30	.111	17.0
1928	1.73	.143	20.8	1944	1.29	.108	16.6
1929	1.66	.137	19.7	1945	1.30	.109	16.6
1930	1.60	.132	19.0	1946	1.29	.108	16.3
1931	1.52	.128	18.0	1947	1.31	.113	16.1
1932	1.49	.123	17.6	1948	1.30	.107	15.9
1933	1.46	.122	17.3	1949	1.24	.098	14.9
1934	1.45	.120	17.2	1950	1.19	.094	14.1
1935	1.44	.118	17.0	1951	1.14	.094	13.5

[1] Derived from Federal Power Commission, Consumption of Fuel for Production of Electrical Energy 1951: Report S-100, Washington, D. C., pp. 4, 6, and 9.

Since 1948 the fuel efficiency of all three fuels has improved. In interpreting these declines in fuel consumption, it should be remembered that the United States average reflects the efficiency of equipment installed in earlier as well as recent years. Hence, fuel-consumption statistics will fully reflect technological advance only after a substantial lag. (There is also an element of equipment utilization that is difficult to segregate.)

Railroads.—Fuel-consumption data for railroads are available for a much shorter period than for electric generating stations. Available data are presented in table 11.

During the period covered in table 11, there were no persistent trends in thermal fuel efficiency for each of the fuels shown. The trend has, of course, been to replace coal and fuel oil with diesel oil as the chief energy fuel in the railroad industry. The reasons for this shift include lower fuel costs and greater economies in operation. In 1951 the costs of the coal, fuel oil, and diesel oil per thousand gross ton-miles of freight service were 28, 37, and 15 cents, respectively.

1941	8.10	113	1949	1.6	8.54	122
1942	8.23	113	1950	1.6	8.80	120
1943	8.31	117	1951	1.6	8.63	118

[1] Interstate Commerce Commission, Bureau of Transport Economics and Statistics, Fuel and Power Statistics of Class I Steam Railways in the United States (Statements No. M-230).
[2] Consumption prior to 1944 was relatively minor.

FOREIGN TRADE

The export and import data shown in tables 12–18 serve to illustrate several major points of interest. These points involve the shifts over time in international trade patterns and the shift of the United States from a net importer position to a net exporter position, or vice versa, in the case of certain fuels.

TABLE 12.—Fuel imported for consumption in the United States, 1939, and 1945–51 [1]

[U. S. Department of Commerce]

Fuel	1939	1945	1946	1947	1948	1949	1950	1951
Petroleum products (million barrels):								
Crude petroleum	28.6	74.0	87.5	99.3	128.6	154.8	172.7	177.5
Residual fuel oil [2]	2.2	27.7	22.9	32.8	29.9	52.8	99.3	88.2
Gas oil and finished distillate oil	.2	19.9	8.2	3.7	2.3	1.7	2.0	2.3
Total	31.0	121.6	118.6	135.8	160.8	209.3	274.0	268.0
Bituminous coal [3] (thousand net tons)	355.1	467.5	434.7	290.1	291.3	315.0	346.7	291.5

[1] Imports of fuels other than those shown have been minor.
[2] Excluding fuel oil for vessels and aircraft.
[3] Includes slack, culm, and lignite.

TABLE 13.—Fuel exported from the United States, 1939 and 1945–51 [1]

[U. S. Department of Commerce]

Fuel	1939	1945	1946	1947	1948	1949	1950	1951
Petroleum products (million barrels):

The effects of World War II and the war in Korea were reflected in the abnormal coal exports of bituminous coal to Europe. After World War II, when European coal production was still in the process of regaining prewar levels, coal exports from this country to the Netherlands, Belgium, France, and Italy increased sharply over the prewar levels. Similarly, the heightened industrial activity resulting from war in Korea increased coal exports to Europe after these exports had returned to a more normal level during 1949–50.

The defense and increased industrial activity that followed the outbreak of war in Korea also resulted in a rise in United States exports of gas oil and distillate fuel oil. Most of the increase in exports went to Canada, the United Kingdom, Sweden, Mexico, and the Netherlands Antilles.

TABLE 14.—Bituminous coal exported from the United States, 1939 and 1945–51, by major country of destination, in thousands of net tons [1]

[1] Excludes fuel or bunker coal loaded on vessels engaged in foreign trade.
[2] Includes Newfoundland and Labrador.

The data dealing with crude petroleum and residual fuel oil imports and exports strikingly illustrate the shift in the United States import-export position in these fuels. During the period 1939 through 1951 the United States changed from a net exporter of crude petroleum and residual fuel oil to a net importer of these two major petroleum items. During this same period the Middle East and Venezuela grew considerably in importance as areas of supply for crude and residual, whereas Mexico and Colombia diminished in importance.

Though the United States imports only negligible quantities of natural gas, as of 1951, United States exports of natural gas to Canada and Mexico have grown in importance.

PART II. COMMODITY REVIEWS

Abrasive Materials

By Henry P. Chandler and A. L. Marks

GENERAL SUMMARY

INCREASED production was reported in nearly all branches of the abrasive industry during 1951, and new records were established in the output of the following natural abrasives: Quartz, ground sand and sandstone, pumice and pumicite, garnet, and emery. In the artificial abrasive field record production was made of silicon carbide and metallic abrasives, and aluminum oxide production almost equaled the record output of 1943.

Imports of industrial diamonds increased 9 percent by weight and 26 percent in total value over the 1950 figures. Corundum imports during 1951 increased 38 percent in tonnage and 40 percent in value over the preceding year.

TABLE 1.—Salient statistics of the abrasives industry in the United States, 1950–51

	1950		1951		Percent of change	
	Short tons	Value	Short tons	Value	Short tons	Value
Natural abrasives (domestic) sold or used by producers:

Exports		[4] 16,175,052		25,157,033		+56

[1] Average annual figure for 1949–51 was 274,070 short tons valued at $7,577,119; annual data not published separately in this case to avoid disclosing individual company operations.
[2] Tonnage not recorded.
[3] Includes Canadian production.
[4] Revised figure.

This chapter includes data for most materials used for abrasive purposes, but certain clays, carbides, oxides, and other substances noted in the Miscellaneous Mineral-Abrasive Materials section are not covered. Certain abrasive products for which figures are given also have important nonabrasive uses.

NATURAL SILICA ABRASIVES

Diatomite.—The production of diatomite continued to increase during 1951. To avoid disclosing individual company operations, the Bureau of Mines, in this case, does not publish the annual data separately; however, the average production for 1949–51 was 274,000 short tons, valued at $7,577,000. This compares with an average of 214,000 short tons valued at $4,307,000 for 1945–47, an increase of 28 percent in tonnage and 76 percent in value.

During 1951 diatomite was produced for sale in three States—California, Nevada, and Oregon. Production in Washington was temporarily suspended.

The principal uses of diatomite in 1951 were: Filtration, 54 percent; fillers, 27 percent; insulation, 12 percent; abrasives, 2 percent; and other uses, 5 percent.

It was reported that two companies producing diatomite in California increased their productive capacity.[1] A description of current mining and processing methods in California appeared in a mining publication.[2]

As quoted in E&MJ Metal and Mineral Markets, prices of diatomite during 1951 continued unchanged from the previous year as follows (per ton, crude, in bulk, dried, nominal): Nevada, f. o. b. mill, 98- to 100-mesh, $25; low-temperature insulation, $25; high-temperature insulation, $40; fine abrasive, 2 to 3 cents a pound (bags extra); California, filtration grades, $20 to $50 f. o. b. mill.

The Geological Surveys of Queensland, Australia, and Nova Scotia, Canada, described newly developed deposits of diatomite in those Provinces,[3] and an occurrence of diatomite in India was the subject of a consular report.[4]

Tripoli.—The sales of tripoli, amorphous silica, and rottenstone totaled 37,476 short tons valued at $1,105,000, a decrease of 14 percent in tonnage and 6 percent in value from the 1950 figures. These commodities were produced in Illinois, Missouri, and Pennsylvania.

The quantity of tripoli used as an abrasive decreased 20 percent in 1951 from 1950. The other uses—for fillers, foundry facing, etc.—increased slightly.

Companies producing tripoli, amorphous silica, and rottenstone in 1951 were: Ozark Minerals Co., Cairo, Ill. (amorphous silica); Tamms Industries, Inc., 228 North LaSalle St., Chicago 1, Ill. (amorphous silica); American Tripoli Corp., Seneca, Mo. (tripoli); Penn Paint & Filler Co., Antes Fort, Pa. (rottenstone); and Keystone Filler & Mfg. Co., Muncy, Pa. (rottenstone).

Quotations on tripoli in E&MJ Metal and Mineral Markets remained unchanged from 1950, as follows (per short ton, paper bags, minimum carlot 30 tons, f. o. b. Missouri): Once-ground through 40-mesh, rose and cream, $30; double-ground through 110-mesh, rose and cream, $32; air-floated through 200-mesh, $35.

1951	28.000	869,000	7,000	155,000	2,476	81,135	37,476	1,105,135

[1] Including amorphous silica and Pennsylvania rottenstone.
[2] Partly estimated.

Quartz.—Total sales of crude, crushed, and ground quartz from pegmatite veins or dikes and from quartzite in 1951 increased 75 percent in tonnage and 65 percent in value compared with 1950. The principal uses for which the reported tonnage was consumed included glass and ferrosilicon, with smaller quantities for abrasives, filters, pottery, tile, and miscellaneous. Sales of crude quartz declined from 1950, but sales of crushed and of ground quartz increased substantially. These data do not include the sales of quartzite to cement mills and certain sales of quartz or quartzite for use in the manufacture of ferrosilicon.

The average value of the quartz reported in this section was $4.15 per ton in 1951, compared with $4.40 in 1950 and $4.42 in 1949.

TABLE 3.—Quartz (crude, crushed, and ground) sold or used by producers in the United States, 1947–51 [1]

Year	Crude		Crushed		Ground [2]		Total	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1947	21,940	$118,231	62,169	$170,254	17,208	$136,040	101,317	$424,525
1948	41,081	250,184	104,496	374,781	16,284	125,702	161,861	750,667
1949	15,816	74,562	72,432	257,213	19,304	143,716	107,552	475,491
1950	11,062	52,591	117,499	430,256	31,947	223,877	160,508	706,724
1951	8,236	23,098	237,806	890,918	35,005	251,354	281,047	1,165,370

[1] Does not include sales of quartzite to cement mills or certain sales of quartz or quartzite for use in the manufacture of ferrosilicon.
[2] To avoid duplication, the ground material shown here is only that ground by the original producers of the crude quartz or by grinders who purchase from small miners not reporting their production.

The combined production of quartz in California and Oregon in 1951 showed a substantial increase over 1950, both in tonnage and value.

A discovery of a quartz deposit of excellent quality in Utah was reported,[5] and significant developments in quartz-crystal synthesis were recorded during 1951.[6]

Ground Sand and Sandstone.—Sales of ground sand and sandstone in 1951 increased 9 percent in tonnage and 11 percent in value over 1950. The average value per ton in 1951 was $8.75, compared with

$8.61 in 1950 and 1949. Illinois, the State producing the largest tonnage, accounted for 32 percent of the total, its output declining slightly in tonnage, but increasing a little in value over the preceding year. New Jersey, which ranks second as a producer, with 18 percent of the total, reported small increases both in tonnage and value over 1950. Idaho showed a relatively large increase in tonnage and value, but little change was noted in the other producing States.

Grand total	818,479	7,163,343	8.75

[1] Include paint, plaster, roofing, and siding.

Abrasive Sands.—Considerable tonnages of natural sands with a high silica content are sold for abrasive purposes, such as glass grinding, stone polishing, and sand blasting. Sales of these sands in 1951 totaled 1,476,912 short tons valued at $3,111,649, compared with 1,299,760 tons valued at $2,670,791 in 1950. The 1951 figures include 549,955 short tons of blast sand valued at $1,875,775, compared with 470,717 short tons valued at $1,463,623 in 1950. The quantity and value of these sands are included in the figures given in the Sand and Gravel chapter of this volume where detailed data regarding tonnages produced in each State appear.

SPECIAL SILICA-STONE PRODUCTS

Grindstones and Pulpstones.—Sales of grindstones in 1951 increased 25 percent in tonnage and 36 percent in value over 1950, but the sales of pulpstones declined in both quantity and value. Ohio and West Virginia were the only States reporting the manufacture of grindstones, and pulpstones were produced only in Washington.

TABLE 8.—Grindstones and pulpstones sold by producers in the United States, 1947–51

Year	Grindstones		Pulpstones		
	Short tons	Value	Quantity		Value
			Pieces	Equivalent short tons

Oilstones and Other Sharpening Stones.—Output of natural sharpening stones increased during 1951. The Bureau of Mines is not at liberty to publish the exact figures because of the small number of producers. Producing States in 1951 were: Arkansas—oilstones and whetstones; Indiana—whetstones, hones and rubbing stones; New Hampshire—scythestones; Ohio—rubbing stones (holystones).

Millstones.—Only one company, in North Carolina (Rowan County) reported production of millstones in the United States during 1951, and no chasers were manufactured.

TABLE 9.—Value of millstones and chasers sold by producers in the United States, 1946–51 [1]

Year	Number of producers	Value	Year	Number of producers	Value
1946	4	$14,780	1949	2	$9,400
1947	4	23,189	1950	2	11,300
1948	3	17,733	1951	1	6,000

[1] Produced in New York (1946–48 only), North Carolina, and Virginia (except 1951).

Grinding Pebbles and Tube-Mill Liners.—The combined output of grinding pebbles and tube-mill liners in 1951 increased 30 percent in tonnage and 40 percent in value over the previous year. Grinding pebble production was reported from the following States: Minnesota, Wisconsin, Texas, North Carolina, and Washington; and tube-mill liners from Minnesota, Wisconsin, and North Carolina.

TABLE 10.—Grinding pebbles and tube-mill liners sold or used by producers in the United States, 1947–51

Year	Grinding pebbles		Tube-mill liners		Total	
	Short tons	Value	Short tons	Value	Short tons	Value

NATURAL SILICATE ABRASIVES

Pumice and Pumicite.—Production of pumice and pumicite (volcanic ash) in 1951 increased 4 percent in tonnage and 3 percent in value over 1950. Its principal use as in prior years was as aggregate in lightweight concrete.

TABLE 11.—Pumice and pumicite sold or used by producers in the United States,[1] 1946–51

Year	Short tons	Value	Year	Short tons	Value

[1] Included with "Other States" to avoid disclosure of individual company operations.
[2] Alaska (1951), Arizona (1949 and 1951), Colorado (1950–51), Kansas, Montana (1950–51), Nebraska (1950–51), Nevada (1950–51), Oklahoma (1949–50), Texas, and Utah (1949).

Pumice and pumicite production was reported from 14 States and Alaska, the largest producer being California, with New Mexico second. The largest increase was reported from California, whereas marked declines in production were noted in New Mexico and Oregon.

Average values per ton at the mine were as follows: 1951, $3.67; 1950, $3.70; 1949, $3.31; 1948, $4.12.

TABLE 13.—Pumice and pumicite sold or used by producers in the United States, 1949–51, by uses [1]

Use	1949		1950		1951	
	Short tons	Value	Short tons	Value	Short tons	Value

Total	716,742	2,369,082	719,356	2,661,052	749,942	2,752,907

[1] Includes Alaska.
[2] Insecticide, insulation, brick manufacture, filtration, solvents, roads (surfacing and ice control), absorbents, soil conditioner, and miscellaneous uses.

The tonnage of pumice and pumicite used for concrete admixture and concrete aggregate increased 7 percent in quantity and 14 percent in value over the preceding year. The pumice used for abrasive purposes in 1951 was less than one-half the amount so used in 1950. As an admixture in acoustic plaster its use also declined, but for minor industrial uses the tonnage increased slightly. These minor uses included insecticides, insulation, brick manufacture, filtration, solvents, roads (surfacing and ice control), absorbents, soil conditioning, and other miscellaneous applications. (*See* fig. 1.)

As reported in Oil, Paint and Drug Reporter, quotations on domestic and imported pumice in 1951 showed but little change over the previous year, and were as follows: Domestic coarse-ground (sizes 0, ½,

Digitized by Google

1, 1½, 2, and 3)—in bags, ton lots, New York, 3⅝ to 4½ cents a pound, smaller lots, 3⅞ to 4½ cents; imported—Italian, silk-screened, fine, in bags, ton lots, 4 cents a pound; coarse, 6½ cents; sun-dried—fine or coarse in bags, ton lots, 2½ cents; pumice—in barrels, ½ cent a pound higher. The E&MJ Metal and Mineral Markets quoted per pound, f. o. b. New York or Chicago, in barrels, powdered, 3 to 5 cents; lump, 6 to 8 cents.

The use of pumice imported from Europe in the manufacture of masonry units was described.[7] The enactment of legislation to make available pumicite (volcanic ash) from portions of the Katmai National Monument in Alaska as a source of needed building material was considered.[8] New types of lightweight masonry units using pumice were described in a booklet.[9] The pumice industry in Oregon was the subject of an article in a technical magazine.[10]

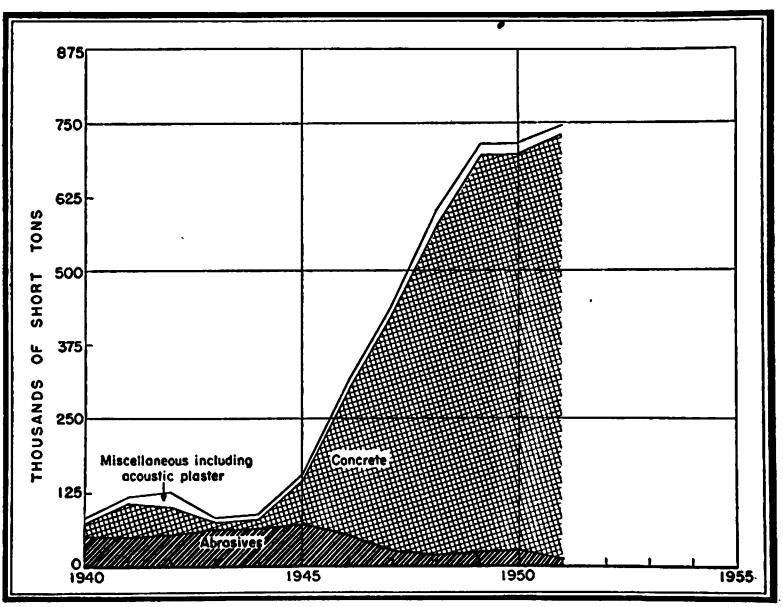

FIGURE 1.—Pumice and pumicite sold or used in the United States, 1940–1951, by uses.

Garnet.—Garnet production in 1951 was 14,050 short tons valued at $1,247,000, an increase of 51 percent in tonnage and 57 percent in value over 1950. This was the largest annual production of garnet on record. Sales of the fine sizes of garnet to the optical and other industries for glass and metal polishing increased during the year. Use of the coarser sizes of garnet for sand blasting also increased. Garnet production in Idaho gained substantially. The largest commercial use for garnet continued to be for the manufacture of garnet-coated abrasive papers and cloths. A description of the new equipment for

garnet production at the Barton mines, North Creek, N. Y., appeared in a trade publication.[11]

A description of the industrial uses of garnet appeared in a trade journal. Production methods were described, and it was suggested that if the price were reduced uses would increase considerably.[12]

TABLE 14.—Abrasive garnet sold or used by producers in the United States, 1946–51

Year	Short tons	Value	Year	Short tons	Value
1946	7,743	$570,186	1949	6,578	$505,231
1947	8,722	614,071	1950	9,304	793,558
1948	8,039	587,797	1951	14,050	1,246,947

As quoted in E&MJ Metal and Mineral Markets, the price of New York Adirondack garnet concentrate in grain form during 1951 was $93 a short ton.

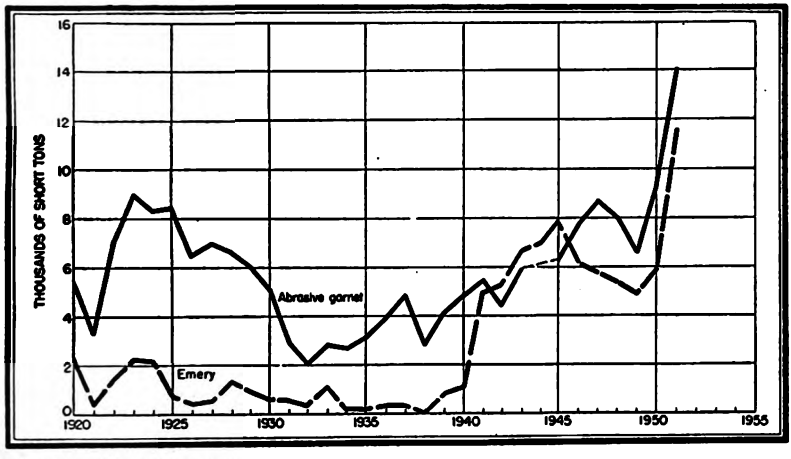

FIGURE 2.—Abrasive garnet and domestic emery sold or used by producers in the United States, 1920–51.

NATURAL ALUMINA ABRASIVES

Corundum.—During 1951 the Union of South Africa produced about 5,000 short tons of corundum concentrates, of which 4,893 short tons, valued at $273,095, was imported into the United States compared with 3,543 short tons valued at $194,427 during the previous year. Neither the United States nor Canada had produced corundum in recent years. The American Abrasive Co. of Westfield, Mass., continued to be the only importer. An article commenting on the corundum supply and the uses of corundum appeared in a trade journal.[13]

Corundum and emery were the subjects of an article in a mining magazine.[14]

Prices of imported corundum concentrates have not been quoted in the trade press. Average value of the corundum concentrates imported in 1951, as shown in the import statistics, was $55.81 per short ton, compared with $54.88 in 1950.

Quotations on natural corundum grain in 1951, as given in the E&MJ Metal and Mineral Markets, remained unchanged from the previous year and were as follows: Per pound, sizes 8 to 60, inclusive, 8½ cents; 70 to 275, inclusive, 9½ cents; 500, 28 cents; 850, 43 cents; 1,000, 45 cents; 1,200–1,600, 65 cents; and 2,600, 70 cents.

[1] In addition to countries listed, corundum is produced in U. S. S. R., but data on production are not available; estimate is included in the total.
[2] Data not available; estimate by author of chapter included in total.
[3] Reported as corundum and emery (believed to be largely emery).
[4] Recovered from tailing dumps.
[5] Estimate.
[6] Revised figure.

Emery.—Domestic production of emery in 1951 advanced sharply over 1950 figures, the output being 11,634 short tons valued at $160,000 compared with 5,949 short tons valued at $75,000, increases of 96 percent and 113 percent, respectively. Importations of emery in 1951 also showed an increase to 2,810 short tons, valued at $33,519 compared with 1,726 short tons valued at $21,560 in 1950. The producers of emery in the United States in 1951, as in recent years, were Joe DeLuca and DiRubbo & Ellis, both of Peekskill, N. Y. Because of its marked resistance to wear, a large part of the domestic output is used as a nonskid agent in concrete steps and floors. The balance is used for other abrasive purposes. Sales since 1921 are presented graphically in figure 2.

As quoted in E&MJ Metal and Mineral Markets, the price in 1951 of domestic crude ore, first grade, was $12 a ton f. o. b. New York. Grain emery in 1951 (f. o. b. Pennsylvania in 350-pound kegs) was 10 cents a pound for Turkish and Naxos grain and 6½ cents a pound for American grain. These prices were unchanged from the previous year.

INDUSTRIAL DIAMONDS

World production of industrial diamonds in 1951 was approximately 14 million carats, an increase of 11 percent over 1950. The Belgian Congo continued to be the largest producer—over 10,000,000 carats, or about 72 percent of the industrial diamond world supply. Other large diamond-producing areas, in order of production, were: Union of South Africa, Gold Coast, Portuguese Angola, and Sierra Leone. No industrial diamonds were mined in the United States.

Importations into the United States of industrial diamonds of all classifications during 1951 totaled 12.2 million carats valued at $46.7 million, an increase of 9 percent by weight and 26 percent in value over the preceding year. This represented about 86 percent of the world production of industrial diamonds.

The United States Government continued to purchase industrial diamonds for the National Stockpile.

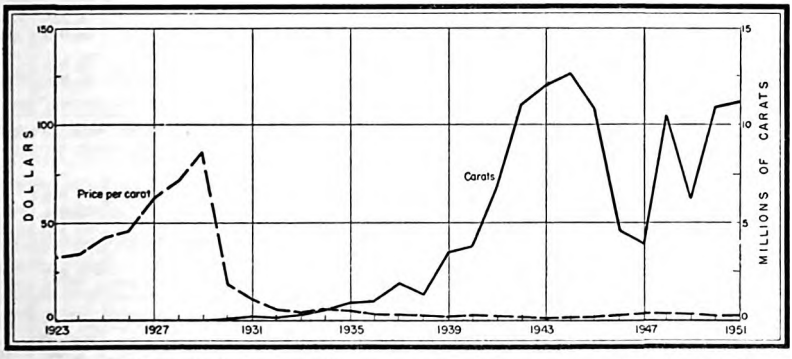

FIGURE 3.—United States imports and average price per carat of industrial diamonds, 1923–51.

Owing to the increased demand for industrial diamonds, the DeBeers Consolidated Mines, Ltd., of South Africa was reopening some of its properties that had been closed for a number of years,[15] and recent activity in an old diamond field in India was noted.[16] A firm of industrial diamond dealers made its first payment on a loan by the Economic Cooperation Administration for development of industrial diamond production in French Equatorial Africa. The loan was mainly for earth-moving equipment.[17]

Over 95 percent of all industrial diamonds imported into the United States passed through the sales agent for the principal African pro-

ducers—the Industrial Distributors, Ltd., a South African corporation and a subsidiary of the DeBeers Consolidated Mines, Ltd. The largest producer of industrial diamonds is the Forminière, a company operating in the Belgian Congo. It has a sales contract with Industrial Distributors, Ltd., which runs until the end of 1955.[18] World demand exceeded the sales offerings [19] and an increase in the price of all classifications of industrial diamonds was announced.[20]

[1] Revised figures.

scribed,[22] as well as methods for crushing bort and other types of industrial diamonds.[23]

The role of the diamond in engineering [24] and the important industrial uses of diamonds [25] were the subjects of recent reviews. The use of industrial diamonds in the ceramic and glass industries was increasing,[26] and grinding of large optical parts with diamonds had become a recognized practice,[27] as well as the use of diamond-impregnated tools for cutting concrete.[28]

A review of new techniques employed in diamond-core drilling and a study of diamond drilling costs [29] and a description of the reconditioning of diamond coring bits were published.[30] Recovery of small diamonds and diamond scrap from grinding was the subject of several articles.[31]

ARTIFICIAL ABRASIVES

The combined tonnage of aluminum oxide and silicon carbide manufactured in the United States and Canada in 1951 increased 54 percent and its value 72 percent over the previous year's production. Aluminum oxide showed a 54-percent increase in tonnage and a 79-percent increase in value, its tonnage nearly equaling that of the record year 1943 and its value considerably exceeding that of 1943. Included with the aluminum oxide were 27,262 short tons of "white high-purity" material valued at $3,749,670 compared with 20,188 short tons valued at $2,607,590 in 1950, an increase of 35 percent in quantity and 44 percent in value for that item. The tonnage of aluminum oxide used for refractories was 4 percent, compared with 2 percent in 1950. A record production of silicon carbide was achieved in 1951—100,498

Digitized by Google

short tons valued at $11,735,000—a gain of 55 percent in quantity and 61 percent in value over 1950. Forty-six percent of the silicon carbide manufactured in 1951 was used for refractories compared with 24 percent in the previous year. The marked increase in the use of silicon carbides in refractories was indicated by a tonnage of 45,862 for that purpose in 1951, an increase of nearly 300 percent over the corresponding figure for 1950.

The output of metallic abrasives in the United States in 1951 increased 14 percent in quantity and 53 percent in value over 1950.

TABLE 19.—Crude artificial abrasives produced in the United States and Canada, 1947–51

Year	Silicon carbide [1]		Aluminum oxide [1] (abrasive grade)		Metallic abrasives [2]		Total

[2] Shipments from United States plants only.

TABLE 20.—Stocks of crude artificial abrasives and capacity of manufacturing plants, as reported by producers in the United States and Canada, 1947–51, in short tons

Year	Silicon carbide		Aluminum oxide		Metallic abrasives [1]	
	Stocks Dec. 31	Average annual capacity	Stocks, Dec. 31	Average annual capacity	Stocks, Dec. 31	Average annual capacity
1947	3,524	72,350	32,977	233,500	9,987	245,479
1948	5,387	73,250	34,177	233,500	9,907	240,129
1949	21,964	81,121	49,505	237,072	10,144	231,650
1950	8,766	84,398	22,025	238,500	7,291	209,850
1951	11,786	106,741	32,428	249,000	9,843	244,178

[1] Figures pertain to United States plants only.

Stocks of aluminum oxide increased 47 percent, silicon carbide 34 percent, and metallic abrasive 35 percent from the 1950 figures. The ratio of production to annual plant capacity of silicon carbide was 94 percent (77 percent in 1950), for aluminum oxide, 87 percent (59 percent in 1950). Metallic abrasives showed a production of 68 percent of plant capacity, a slightly lower ratio than in 1950.

To conform with antitrust laws, a group of manufacturers was ordered by a Federal Court to dissolve a selling organization for coated abrasive products after 22 years activity. They were required to end their joint ownership in coated abrasive factories in Canada, Great Britain, Germany, and Brazil.[32]

Standardization and simplification in the coated abrasive industry was the subject of a recent article.[33]

[32] Business Week, No. 1120, Feb. 17, 1951, p. 146.

Digitized by Google

A new electric furnace plant to manufacture silicon carbide abrasives was started at Cap-de-la-Madeleine, Quebec.[34]

One of the larger abrasive manufacturers was planning a 30-percent expansion of its silicon carbide production.[35]

Recommendations for the correct mounting and use of abrasive grinding wheels, based on tests at a number of large manufacturing plants, were made by the Grinding Wheel Institute.[36]

According to a study reported in 1951 of abrasive grinding operations in Germany, about 1 kilogram (about 2 pounds) of grinding-wheel material was consumed for every ton of iron (or steel) produced in that country. The increase expected in West European steel production would, it was believed, lead to a corresponding boom in the grinding-wheel industry.[37]

Steps in grinding, lapping, and polishing of steel balls for use in ball bearings were described in the technical press.[38]

Abrasive tumbling as a precision finishing method was the subject of a paper presented at the 37th annual convention of the American Electroplaters' Society.[39]

Rapid finishing of steel machine parts by the use of cloth abrasive belts was recommended for a number of operations.[40]

MISCELLANEOUS MINERAL-ABRASIVE MATERIALS

In addition to the natural and manufactured abrasive substances for which data are included in other sections of this chapter, many other mineral materials have been used for abrasive purposes. A number of oxides, including tin oxides, magnesia, iron oxides (rouge and crocus), cerium oxide, chromium oxide, and manganese oxide, have been employed as polishing agents. Zirconium silicate and calcined kaolin have been suggested for polishing optical glass. Certain carbides, such as boron carbide and cemented carbides, which include tantalum carbide, titanium carbide, and tungsten carbide, have been used for their abrasive properties, especially when extreme hardness or durability are demanded. Other substances with abrasive applications include finely ground and calcined clays, lime, talc, ground feldspar, river silt, slate flour, and whiting.

FOREIGN TRADE [41]

Imports.—The total value of imports for consumption of both natural and artificial abrasives during 1951 increased 34 percent over the preceding year. Large gains, percentagewise, were shown in the importation of industrial diamonds, in artificial abrasives, and in manufactured abrasive products. Only in minor instances were decreases noted.

Exports.—The value of natural and artificial abrasives exported during 1951 was $25.2 million, an increase of 56 percent over 1950.

Aluminum

By Delwin D. Blue

GENERAL SUMMARY

PRODUCTION of aluminum increased in 1951, not only in the United States but in virtually every producing country of the world. The 1951 record postwar production reflected the unstable political conditions that existed in that year, the high demand for aluminum for defense purposes, the increased substitution of aluminum for other metals that were in more critical supply, and the application of aluminum in new uses through improved production techniques.

In the United States virtually all consumption of aluminum was under Government control, prices were controlled by ceiling price regulations, and steadily increasing tonnages were going into defense uses. A vast expansion program was in progress that when completed would approximately double capacity for primary aluminum production compared with 1949. The total new supply of aluminum (production, secondary recovery, imports) increased less than 6 percent, even though primary production and secondary recovery increased substantially, because of decreased receipts of aluminum from foreign sources. A decrease in exports was caused by the high demand for aluminum in the United States.

TABLE 1.—Salient statistics of the aluminum industry in the United States, 1946–51

	1946	1947	1948	1949	1950	1951
Primary production [1] short tons	409,630	571,750	623,456	603,462	718,622	836,881
Value	$115,812,000	$161,626,000	$180,755,000	$190,303,000	$235,977,000	$305,074,000
Quoted price per pound cents	15.0	15.0	15.7	17.0	17.7	19.0
Secondary production short tons	278,073	344,837	286,777	180,762	243,666	292,608
Imports	$12,463,960	$6,603,722	$42,203,519	$36,815,965	$68,565,400	$63,465,000
Exports	$20,284,053	$52,231,972	$43,219,940	$32,924,653	$22,153,000	$19,260,000

[1] Revised figure.

In 1951 a major development occurred in the antitrust suit initially begun in 1937 against the Aluminum Co. of America. A Federal district court entered a judgment which directed the sale of over a million shares of stock of Aluminum, Ltd., within a period of 10 years and the transfer of the voting rights of over a half million shares to 3 court-appointed trustees, prohibited the sale of more than 50,000

Digitized by Google

shares to any one person unless the Attorney General was first notified, and required those obligated to dispose of stocks to report regularly to the trustees. The court reserved jurisdiction over the case if stock disposals during the next 5 years failed to establish competition within the aluminum industry.

A large part of the hearings before the Subcommittee on Study of Monopoly Power (Celler Committee) of the United States House of Representatives, January 22 to February 9, was devoted to the aluminum-production situation.[1]

GOVERNMENT REGULATIONS

The uses and distribution of aluminum during 1951 were largely controlled by orders and regulations issued by the National Production Authority of the United States Department of Commerce under authority of the Defense Production Act of 1950. (See section on Prices for discussion of price regulations.) NPA Order M–5, Rated Orders for Aluminum (issued in October 1950), continued in force as amended. On July 1, when the Controlled Materials Plan for aluminum, copper, and steel went into effect, Order M–7 (which had been issued in November 1950) was revoked, and its provisions were incorporated in NPA Order M–47–A. At the end of 1951 the following were the more important NPA orders and regulations applying to aluminum:

Order M–5, Rated Orders for Aluminum, provided rules for accepting and scheduling authorized controlled material orders and rated orders for aluminum.

M–22, Aluminum—Distribution of Aluminum Scrap, regulated the segregation, acceptance, delivery and distribution of aluminum scrap and prohibited undue accumulations of such scrap.

M–47–A, Use of Iron and Steel, Copper and Aluminum in Certain Consumer Durable Goods and Related Products, limited the use of iron and steel, copper, and aluminum in the manufacture of specified goods in order to promote equitable distribution of the limited quantities of these metals remaining after provision for defense and defense supporting activities.

M–67, Aluminum Foil in Containers or Packaging Material, placed restrictions upon the use of aluminum foil in rigid or flexible containers, wrappers, bags, and envelopes and specified quantity limitations in the use of aluminum foil for packaging various classes of products.

M–84, Aluminum for Destructive Purposes, restricted the use of aluminum for destructive purposes to the minimum amount and lowest grade necessary for the particular use.

M–88, Aluminum Distributors, provided means whereby aluminum distributors might obtain replacements of their stock and specified tonnage and item limitations for authorized and unauthorized material orders.

Regulation 2, Basic Rules of the Priorities System, stated what kind of orders are rated orders, how to place them, and the preference status of such orders.

All of the Controlled Materials Plan regulations were applicable to aluminum and aluminum products. CMP Regulations 1 to 7 were in force at the end of 1951.

Other NPA orders placed limitations on the use of aluminum for specific applications as indicated by the order titles: Order M–26, Packaging Closures; Order M–27, Collapsible Tubes; and Order M–50, Electric Utilities.

DOMESTIC PRODUCTION

Output of aluminum in the United States in 1951 was exceeded only by the peak war year 1943 and totaled about 1,129,000 short tons despite strikes and power shortages that hampered production. Production of primary metal provided 74 percent, metal recovery from new scrap 19 percent, and old scrap 7 percent of the total. The Government-initiated expansion program was increased from 446,000 to 677,000 annual tons of new capacity. One new plant initiated production in December; expansion of three established plants was realized; and previously installed capacity, which had been idle for lack of power, was put into production, using high-cost subsidized power. The recovery of aluminum from new scrap also increased.

Primary.—Domestic production of primary aluminum in 1951 was 837,000 short tons, an increase of 16 percent over 1950. The only previous year with greater production was 1943, which was at the height of World War II, when a number of Government-owned reduction plants, constructed for emergency operation and using high-cost power, were in operation.

Production has increased in each succeeding quarter beginning with the first quarter of 1950; during August, the peak month in 1951, production was 73,816 short tons.

TABLE 2.—Production of primary aluminum in the United States, 1949–51, by quarters, in short tons

	1949	1950	1951
1st quarter	157,957	161,213	200,716
2d quarter	165,169	180,353	202,875
3d quarter	157,520	185,973	215,943
4th quarter	122,816	191,083	217,347
Total	603,462	718,622	836,881

At the end of 1951, 12 reduction plants (Massena and St. Lawrence, N. Y., considered 1 plant) were in operation. The plant at Chalmette, La., initiated operation on December 10, 1951, but the production from this plant added very little to the yearly total. The increased production for 1951 over 1950 came mainly from plants at Point Comfort, Tex.; Jones Mills, Ark.; Spokane, Wash.; and St. Lawrence and Massena, N. Y. The Point Comfort plant operated for its first full year. Four potlines at Jones Mills were operated throughout the year for the first time since World War II, and in addition a fifth line constructed under the expansion program began to produce in June. At Spokane a seventh potline was added, and additional pots were put on existing lines. By using high-cost power, production was increased at the St. Lawrence and Massena, N. Y., plants. Equipment that had previously been idle was placed in operation. Other plants part of whose production was obtained by use of high-cost Government-subsidized power were those at Alcoa, Tenn., Badin, N. C., and Listerhill, Ala. Because of the low water conditions and insufficient quantities of high-cost power in the Tennessee Valley, significant increases in production were not realized at these plants.

Digitized by Google

Factors responsible for production losses were strikes at two plants of the Reynolds Metals Co., and power shortages in the Pacific Northwest and in the Tennessee Valley. Strikes occurred at Reynolds' Listerhill, Ala., plant in May and at the Troutdale, Oreg., reduction works on December 12. The production loss from these 2 strikes was approximately 8,000 tons. Union contracts that expired in 1951 were extended pending the outcome of wage hearings before the Wage Stabilization Board.

A power shortage in the Pacific Northwest caused a partial shutdown of reduction facilities in Oregon and Washington during the latter part of September. On September 10 the Defense Electric Power Administration issued DEPA Order EO–4, which provided for orderly steps to be taken to meet varying degrees of power shortages and to achieve optimum power distribution in the interest of national defense. In case of power curtailment, the first 225,000 kw. was to be taken from the aluminum industry.

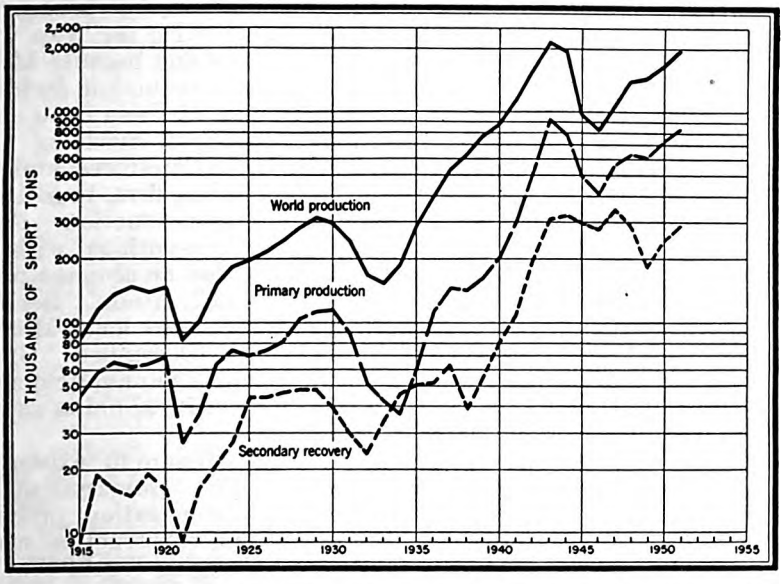

FIGURE 1.—World and domestic primary production and domestic secondary recovery of aluminum, 1915–51.

On September 18 two potlines were closed down, one at Kaiser's Spokane, Wash., plant and the second at Alcoa's Vancouver, Wash., works. Reynolds kept its facilities at Troutdale, Oreg., and Longview, Wash., in operation by substituting steam-generated power for curtailed hydroelectrical power. Full power was returned to the reduction plants on October 3; production losses were estimated at 3,000 tons.

Digitized by Google

Expansion.—Under the authority of the Defense Production Act of 1950 the Government had initiated in that year an expansion program planned to create enough new capacity to meet essential civilian and military requirements and leave a surplus for stockpiling. New facilities required to meet these demands were variously estimated at 500,000 to 1,000,000 tons of production capacity per year at the start of the expansion program; as the defense program progressed, the estimated demand increased.

At the beginning of 1951 negotiations were underway between the Government and 5 concerns for constructing new production facilities with an aggregate annual capacity of 446,000 tons. During 1951 this projected capacity was increased to 677,000 annual tons, and the distribution among the various producers was changed. At the inception of the expansion program it was deemed advisable to bring as many new producers as possible into the aluminum industry to promote a more competitive structure. A number of industrial concerns, largely established metal fabricators or secondary producers investigated the possibilities of producing aluminum, but because of the large capital investment required for constructing facilities with capacities large enough for economical production and because of the integration of mining, alumina production, and reduction facilities that had been established in the industry, most of these companies withdrew from the program. However, the Apex Smelting Co., Chicago, Ill., a large, secondary metal (nonferrous) producer, and the Harvey Machine Co., Torrance, Calif., a fabricating firm, negotiated with the Government for entry into aluminum production. Apex withdrew from the program early in 1951; Harvey negotiated with the Reconstruction Finance Corp., for funds to establish an alumina plant in Washington and a reduction plant at Kalispell, Mont. Because of difficulties encountered in obtaining a Government loan, Harvey joined with the Anaconda Copper Mining Co. in December. Under the joint venture a reduction plant with 72,000 tons annual capacity was planned for construction at Kalispell, Mont., with alumina supply to come from other producers.

All new facilities included in the primary-aluminum expansion program were being financed with private funds. Government aid was being furnished in the form of accelerated amortization, procurement contracts, and priorities for equipment and construction materials. Unlike some of the facilities constructed during World War II, all of the plants in the 1950–51 program were being designed and located for continued operation in the post emergency period.

Although Alaska was not an aluminum producer and there were no firm plans for production at the end of 1951, this Territory had been suggested with increasing frequency as one of the most promising remaining sites for additional reduction facilities in North America. The Alaska Development Board reported that large hydroelectric power potentials existed at locations having complete natural protection from possible attack and yet readily accessible to ocean navigation. Plant sites in the Skagway-Hains district had been investigated by several primary producers.

[1] Opinion of Judge D. J. Knox, United States District Court, Southern District of New York, Equity No. 85-73, United States of America, plaintiff versus Aluminum Co. of America et al., defendents. Represents economic capacity, having reference to the availability and price of electrical energy.
[2] Economic capacity plus capacity requiring high cost power.
[3] All of this capacity not available until 1954.
[4] Does not include capacity which had become available under the expansion program.

Secondary.—Domestic recovery of aluminum from secondary sources totaled 292,608 short tons in 1951, an increase of 20 percent over 1950. This increase was obtained despite a rollback in scrap and secondary ingot prices (*see* section on Prices) in June which resulted in a reduction in the recovery from aluminum scrap from an average of 25,700 tons per month during the first 6 months of 1951 to 18,800 tons in August and 16,500 tons in September. The highest secondary aluminum recovery was in July because of the time period allowed in the price-rollback order for working out high-priced stocks. During October, November, and December the average monthly recovery from aluminum scrap was 19,600 tons.

Secondary aluminum was recovered from aluminum-base scrap by the three primary producers, about 65 secondary smelters, and several thousand foundries and other consumers. Total secondary aluminum recovery also includes small tonnages of aluminum recovered as an alloying constituent in the smelting of copper-, zinc-, and magnesium-base scrap. The recoverable aluminum content (expressed as alloy equivalent) of new nonferrous scrap was 216,017 short tons, a 29-percent increase over 1950. Recovery from old scrap, however, was approximately the same in 1950 and 1951, 76,358 and 76,591 short tons, respectively. Aluminum-base scrap-

Digitized by Google

consumption distribution was as follows: Primary producers and independent fabricators, 24 percent; foundries and chemicals, 6 percent; and independent secondary smelters, 70 percent.

Detailed information regarding secondary aluminum in 1951 is given in the Secondary Metals—Nonferrous chapter of this volume.

CONSUMPTION

Apparent consumption of primary aluminum in 1951 was 975,000 short tons as computed by adding primary sold or used by producers (production adjusted for stock changes at primary reduction plants) and net imports of ingot, slab, plate, sheet, bar, and other crude and semifabricated forms. This apparent consumption included aluminum going to the National Stockpile but did not reflect stock changes by aluminum-metal consumers.

Secondary aluminum for consumption was obtained from domestic and imported scrap. Imported scrap aluminum was largely in pig form for easier handling and shipping. Aluminum recovered from "loose" imported scrap is included in domestic recovery; but, since this type of material represented a small proportion of the total imports, the factored net scrap imports must be considered as additional metal available for consumption. The recovery of aluminum from net imports of scrap was calculated at 90 percent of the weight.

TABLE 4.—Apparent consumption of primary aluminum and ingot equivalent of secondary aluminum in the United States, 1946–51, in short tons

Year	Primary			Secondary		
	Sold or used by producers	Imports (net) [1]	Apparent consumption [2]	Domestic recovery		Imports (net) [3]
				From old scrap	From new scrap	
1946	435,964	25,913	575,687	90,535	187,538	12,468
1947	570,923	−46,694	571,789	163,847	180,990	13,412
1948	625,834	40,041	684,575	95,648	191,129	64,165
1949	587,532	48,424	635,956	44,596	136,166	35,751
1950	731,087	167,249	898,336	76,358	167,308	60,443
1951	845,392	129,852	975,244	76,591	216,017	16,694

[1] Crude and semifabricated, excluding scrap. May include some secondary.
[2] For 1946–48, apparent consumption modified by changes in stocks held by the Office of Metals Reserve.
[3] Ingot equivalent of net imports (wt. ×0.90). Imports are largely scrap pig. Some duplication of secondary aluminum occurs because of small amount of loose scrap imported which is included as secondary recovery from old scrap.

Shipments of aluminum wrought and cast products, as reported by the Bureau of the Census, totaled 1,153,000 short tons in 1951; 275,000 tons was shipped as castings and 878,000 tons as wrought products.[2] Shipments of cast and wrought products increased only 25,000 tons or 2.2 percent over 1950; an indeterminate amount of this increase was accounted for by increased statistical coverage of shipments of wrought products.[3]

[1] Net shipments consist of total shipments less shipments to other metal mills for further fabrication.

Data on the other major consumption classification were available only for 1950 and 1951. In 1951 consumption of aluminum for dissipative uses was 83,213 short tons, an increase of 11 percent over the 75,060 tons used for the same purposes in 1950. Of the total 1951 "dissipative" consumption (such as deoxidizers, hardeners, and chemicals), 62 percent was consumed as secondary ingot, 27 percent as primary ingot, and the remaining 11 percent in the form of scrap. Forty-nine percent of this total was used for deoxidizing steel, 15 percent in zinc-base alloys, 12 percent in the production of anhydrous aluminum chloride, 4 percent in steel alloying, 3 percent in copper-base alloys, 2 percent in magnesium-base alloys, and the remainder

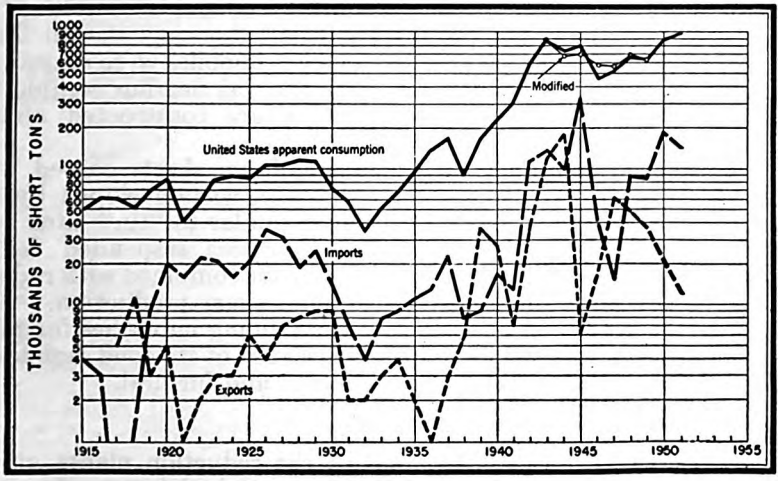

FIGURE 2.—Imports, exports, and apparent consumption of aluminum, 1915–51. Imports and exports do not include scrap.

Digitized by Google

for thermite for welding, in Alnico and nickel alloys, in chemical reactions, galvanizing baths and other minor miscellaneous applications.[4]

USES

During 1951 a large proportion of the aluminum supply went into defense and defense supporting activities. Information on uses to which this metal was put was restricted for security reasons, and an industrial use distribution pattern was not available. Use of aluminum in consumer items such as automobiles, refrigerators, stoves, washing machines, etc., was reduced. In some manufactures steel stampings and castings replaced aluminum; in other instances aluminum parts replaced parts previously made of copper and brass.

Despite the controls placed on the uses of aluminum (*see* section on Government Regulations) new applications were developed. In the electrical field a gradual switch from brass to aluminum bases for electric light bulbs was in progress, and the use of aluminum in flash bulbs, decorative lights, lamps, and distribution transformers was increasing. The Bell Telephone System was experimenting on the use of aluminum wire in communications equipment. A new method of producing light, "electroluminescence," was developed, which utilized neither an incandescent filament nor an evacuated bulb but employed a sheet of glass on one surface of which was applied an electrically conducting coating covered with a suitable phosphor coating and backed with foil. A new glass radiant-heating panel consisted of an aluminum grid about 0.001 inch thick backed with tempered glass and had a maximum heat output of 3 watts per square inch of radiating surface.

New uses for aluminum in the transportation and building-product industries (except for military transport and structures) were curtailed because of the unavailability of this metal. Aluminum radiators for automobiles were widely discussed, but no satisfactory economical methods for assembly had been developed. The La Sabre, an experimental automobile, was on display and contained many light-metal (aluminum and magnesium) parts and assemblies. In addition to cast-aluminum pistons and clutch housing, the oil filter, fuel pump and carburetor bodies in some automobiles were aluminum die castings. The SS. *United States*, which was nearing completion at Newport News, Va., had a superstructure constructed almost entirely of aluminum.

A new type of container, in which aluminum sheets coated with plastic were bonded under heat and pressure, was developed by the Reynolds Metals Co. to make a container similar to "tin" cans now manufactured by the billions. A multi-purpose suspended ceiling consisting of perforated aluminum acoustic pans combined with radiant heating in a steel framework was in pilot-stage production. Aluminum was being tested in the petroleum-refining industries for pipelines, heat exchangers, and condensers because of its good resistance to corrosives, such as sulfides, organic acids, and furfural.

STOCKS

Inventories of primary aluminum at the reduction plants at the beginning of 1951 were 16,636 short tons and had been reduced to

[4] National Production Authority, Research and Statistics Branch, Survey of Aluminum Destructive Uses, 1950–52, Aluminum and Magnesium Division, Aug. 14, 1952. 9 pp

Digitized by Google

8,125 tons by the end of the year; the average rate of production during the last quarter was 2,362 tons per day.

Stocks of ingot at secondary smelters (excluding secondary operations of primary metal producers) decreased from 7,533 tons at the beginning of 1951 to 4,050 tons, equivalent to 1 week's production, on December 31. Stocks of aluminum-base scrap held by secondary smelters, primary producers, fabricators, foundries, and miscellaneous manufacturers decreased from 18,799 short tons to 12,558. Scrap stocks held by consumers at the end of the year represented about 2 weeks' consumption.

Reserves of aluminum in the National Stockpile increased, and a part of the stockpile supply was provided through Government subsidization of production at plants where low-cost power (below 5 mills per kilowatt-hour) was not available. During the last quarter of 1951 the subsidized production was diverted from the stockpile to make up for the production losses caused by the power shortages in the Pacific Northwest. The withdrawal of 10,000 tons from the stockpile was also authorized in December.

Aluminum stocks held by metal producers, primary and secondary, were adequate for supplying aluminum consumers for less than 1 week and were approaching minimum working inventories. Data on aluminum held by fabricators, manufacturers, and distributors were not available, nor were those on scrap-aluminum stocks held in junk yards and by scrap-metal dealers.

PRICES

The base price of primary aluminum ingot, 99 plus percent pure, remained constant at 19 cents per pound, f. o. b. shipping point, throughout 1951. The price of primary aluminum was controlled under the General Ceiling Price Regulation issued January 26, 1951, that established ceiling prices for all commodities and services (except those specifically exempt) upon the basis of prices in effect during the period December 19, 1950, to January 25, 1951, inclusive.

TABLE 6.—Prices of aluminum ingot and other major metals, 1941–51 [1]

Year	Aluminum, primary ingot (cents per pound)	Copper, electrolytic, New York (cents per pound)	Composite finished steel (cents per pound)	Lead, New York (cents per pound)	Zinc, Prime Western, St. Louis (cents per pound)
1941	16.50	11.87	2.65	5.79	7.48
1942	15.00	11.87	2.65	6.48	8.25
1943	15.00	11.87	2.65	6.50	8.25
1944	15.00	11.87	2.65	6.50	8.25
1945	15.00	11.87	2.73	6.50	8.25
1946	15.00	13.92	3.00	8.11	8.73
1947	15.00	21.15	3.42	14.67	10.50
1948	15.74	22.20	3.91	18.04	13.58
1949	17.00	19.36	4.21	15.36	12.15
1950	17.69	21.46	4.40	13.30	13.88
1951:					
1st quarter	19.00	24.37	4.70	17.00	17.50
2d quarter	19.00	24.37	4.71	17.00	17.50

Although all other leading metals (steel, copper, lead, and zinc) were controlled by the same price regulation, increases were granted for lead and zinc during the last quarter of 1951, and steel prices had increased during January. The price of copper (electrolytic at New York) remained constant at 24.37 cents per pound. Yearly average prices for all of these metals increased because of the lower prices in effect during the early periods of 1950.

The price of secondary ingot at the beginning of 1951 was the highest in history. In January 95–5 aluminum-silicon alloy was selling for 33¾ cents per pound; high-grade scrap (2–S clips) was selling at the same price as primary ingot. These prices continued, with small increases and decreases, depending on the grade of ingot and scrap, until July. On June 29, the Office of Price Stabilization issued CPR–54, Aluminum Scrap and Secondary Ingot, which established ceiling prices on aluminum scrap and secondary ingot, and stated, "The ceiling prices in this regulation are designed to correct this situation (price differential between primary and secondary) by rolling back the prices of secondary aluminum ingot and aluminum scrap to levels which reflect the value of their metallic content in terms of the ceiling prices prevailing for primary aluminum." Prescribed periods were allowed for the scrap dealers and secondary smelters to work out their high-cost inventories. The new prices established by the order reduced the average price of scrap by more than 50 percent and of secondary ingot by about 37 percent.

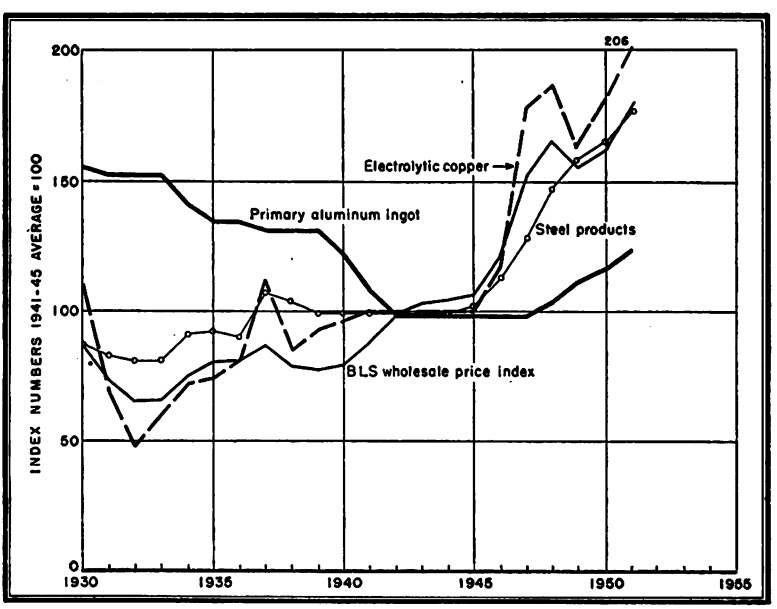

FIGURE 3.—Price of aluminum ingot, electrolytic copper, and finished steel, compared with Bureau of Labor Statistics, general wholesale price index, 1930–51. Index numbers computed for aluminum ingot, electrolytic copper, and finished steel from prices reported by the American Metal Market, Bureau of Labor Statistics Index transposed from 1926 to 1941–45 base.

FOREIGN TRADE [5]

United States foreign trade in aluminum in 1951, as indicated by the total value of exports and imports, declined 8.8 percent from 1950. Exports decreased 13 percent and imports 7.4 percent.

The major United States aluminum-import items were crude metal, major exports semifabricated (semicrude), and manufactured items; however, for the first time in history imports of semicrude aluminum exceeded exports. Foreign trade declined throughout 1951; 67 percent of the exports and 62 percent of the imports were made during the first 6 months. The only foreign-trade classifications of aluminum that showed gains during the last half of 1951 were exports of crude and scrap metal; both had a low yearly tonnage. The per pound value of exported crude and semifabricated aluminum was higher than that of imported materials; exports averaged 22.5 cents per pound for pig, ingot, and slab and 34.3 cents per pound for semifabricated compared with 16.9 and 29.6 cents per pound respectively for imports. Per pound export values for scrap were much lower than for scrap imports (4.5 cents compared to 15.9 cents), reflecting the low grade of exported scrap, mostly borings and turnings, and the high grade of imported scrap, mostly "remelt pig."

Canada continued in 1951 as the major foreign supply of aluminum to the United States. Imports from Canada accounted for 73 percent of the total tonnage of crude and semicrude (semifabricated) aluminum and 14 percent of the value of aluminum manufactures. Crude aluminum (ingot, pig, slab, etc.) imports are the most important in tonnage and value, and Canada supplied 86 percent of this type of metal. The other important (over 500 tons) exporters of crude

[5] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Digitized by Google

aluminum to the United States were: Italy, 7,526 tons; Norway, 3,103 tons; Japan, 2,939 tons; and Switzerland, 502 tons. The distribution of aluminum-scrap imports was: Canada, 26 percent; Japan, 23 percent; Germany, 12 percent; Netherlands, 11 percent; France, 10 percent; New Guinea, 5 percent from surplus war material remaining from World War II, South Pacific Allied operations; United Kingdom, 4 percent; and the remainder from 25 other countries. Canada supplied 38 percent of the semicrude aluminum (plates and sheets); United Kingdom, 21 percent; Italy, 12 percent; Germany, 11 percent; France, Belgium, and Japan, 4 percent each and 5 other countries 6 percent. Countries from which over $100,000 value each in aluminum manufactures was imported, in order of value contributions, were: Italy, Germany, United Kingdom, Canada, Japan, and Switzerland.

The year 1951 marked the fourth successive year in which aluminum exports declined. During 1949, 1950, and 1951 decreasing quantities of crude and semicrude (semifabricated) aluminum were exported while the value of exported aluminum manufactures remained relatively constant, indicating high demand for raw material at home and a steady demand for United States articles abroad. Of the total tonnage of crude and semicrude exported, 64 percent was shipped to countries in the Western Hemisphere. Pig, ingot, slab, and crude aluminum exports were distributed as follows: 31 percent to Canada, 32 percent to Mexico, 25 percent to Argentina, 6 percent to Brazil, 4 percent to other Central and South American countries, 1.6 percent to Israel, and less than ½ percent to France and Greece. The United Kingdom received 95 percent of the exported scrap and most of the remainder went to Canada. Canada also received 28 percent of the semicrude aluminum, Venezuela 14 percent, Mexico 11 percent, Cuba 5 percent, 24 other Western Hemisphere countries 11 percent, Israel 9 percent, Philippines 10 percent, and Indonesia 6 percent; the remaining 6 percent went to 35 countries.

During 1951 the duty on crude aluminum was reduced from 2 to 1½ cents per pound as a result of the Torquay Agreement, effective June 6, 1951. Duties on scrap and semifabricated aluminum were 1½ and 3 cents per pound, respectively, as prescribed in the Geneva Agreement effective January 1, 1948. The 1½-cent-per-pound duty on scrap had been suspended from October 1, 1950, to January 30, 1952, by act of Congress (Public Law 535, 82d Cong.), and scrap aluminum entered duty free throughout 1951.

In November the Defense Production Authority disclosed terms of a complicated trade agreement with the United Kingdom that would divert 11,000 short tons of Canadian aluminum scheduled for delivery to the United Kingdom to the United States. The metal was to be delivered over a 5-month period starting in November. In return, the United States was to allot additional tonnages of finished steel, "premium-priced" steel ingots, and iron and steel scrap to the United Kingdom. The aluminum was to be returned to Canada starting in the last quarter of 1952.

TECHNOLOGY

The techniques used in producing primary aluminum have remained basically the same in recent years. Recent improvements in reduction plants have been largely in improved design and larger production units. New alloys with improved physical properties were developed in 1951, and numerous improvements were made in fabricating techniques.

The location of reduction plants before World War II, was based on the availability of low-cost hydroelectric power. The plant at Jones Mills, Ark., constructed with Government funds during World War II, was the first economic plant to use thermal power and marked the beginning of a new trend in aluminum production. With low-cost power from hydroelectric installations no longer available in the required quantities the aluminum industry turned to thermal power for a number of new plants. Power for 68 percent of the new capacity planned under the Government programmed expansion was to be thermally generated. The added capacity at Point Comfort, Tex., and new installations at San Patricio, Tex., and Chalmette, La., were to use power generated from natural gas. Power for Reynolds' Jones Mill, Ark., plant was obtained from diesel-gas generators and from thermal power purchased from the Arkansas Power & Light Co. The new reduction plant under construction at Arkadelphia, Ark., was to receive five-eighths of its power from the Arkansas Power & Light Co. The Rockdale, Tex., plant was to utilize power generated by burning lignite char.

Hydroelectric installations were to supply the power required for added capacity at plants in the Pacific Northwest at Longview, Spokane, and Tacoma, Wash., and Troutdale, Oreg., and for new reduction plants at Wenatchee, Wash., and Kalispell, Mont. Three-eighths of the power requirements for a new plant at Arkadelphia, Ark., were to be hydroelectric, supplied by the Southwest Power Administration.

Digitized by Google

Although supplies of cryolite, fluorspar, and sulfur were adequate to meet the needs of the aluminum industry during 1951, the introduction of large tonnages of new capacity in 1952 was expected to require large excesses of electrolyte (cryolite) for initial filling and operation of new electrolytic cells. The supply of natural cryolite from Greenland, the only commercial producer of this mineral, was limited. The Government, in conjunction with the primary aluminum producers, was making plans for increasing the supply of synthetic electrolytes during the latter part of 1951. These plans included the construction of new processing facilities, the opening of new fluorspar (used in production of synthetic cryolite) deposits, and the purchase of additional supplies from foreign sources.

The Kaiser Aluminum & Chemical Corp. plant at Chalmette, La., was the first new reduction plant to start production since World War II. When completed, it was expected to be the largest aluminum-production plant in the United States and the second largest in the world, second only to the Aluminum Co. of Canada plant at Arvida, Quebec. The Chalmette plant required about 75 buildings with nearly 35 acres of floor space. Eight potlines composed of 1,152 electrolytic cells (144 per line) and 2 power installations with a capacity of 478,200 kilowatts, equal to nearly one-half of the installed capacity at Hoover Dam, were completed or under construction. The electrolytic cells were equipped with Soderberg type self-baking electrodes. Two potlines were supplied with power from 80 Nordburg Radial engines connected to direct current generators. The other 6 lines were to receive power from a steam power plant that included 15 outdoor-type Foster-Wheeler steam generators, fourteen 25,000-kw. General Electric turbogenerators plus rectifier and transformer facilities for converting the high-voltage alternating current to 700-volt direct current for potline operation. Two smaller, 11,250-kw. generators supplied alternating current for auxiliary services. Both power plants used natural gas, as fuel and gas requirement were to be approximately 50 billion cubic feet annually. Among other material requirements were to be 380,000 tons of alumina per year, 88,000 tons of petroleum coke, 34,000 tons of pitch, 8,000 tons of anthracite, 11,000 tons of fluoride salts, and 50 billion gallons of water.

In 1951 a new "superstrength" alloy temporarily designated as XA78S, was developed through the cooperation of the Aluminum Co. of America, Navy Department, Bureau of Aeronautics, Department of the Air Force, and the aircraft industry. This alloy was an aluminum-zinc-copper magnesium alloy similar to 75S, the highest strength alloy in commercial use, and had approximately 10 percent higher tensile and yield strength, with about the same elongation and fatigue properties. It was available to plane builders for experimental and controlled production use only. Limited tests indicated that the increase in mechanical properties would involve some sacrifice in workability. Alcoa patented a new type of aluminum-wire alloy containing boron (less than 0.5 percent) that was reported to have a better combination of strength and conductivity properties and could be cold-worked from hot-rolled rod without preparatory annealing. An improved aluminum casting alloy, known as ML, was developed

Digitized by Google

at the Materials Laboratory at Wright-Patterson Air Force Base, Dayton, Ohio, that had tensile, creep, and stress rupture properties about one-third higher at temperatures between 500° and 700° F. than other light-metal alloys previously used for cast-aircraft components. Other new aluminum alloys developed were XA54S, a high-strength sheet and plate alloy designed for use in pressure vessels, and B50S–0, featuring easy workability and high fatigue strength for use in the manufacture of coiled tubing. Cupal, a bimetallic sheet, strip or tube of copper clad aluminum was developed and produced in Germany and distributed by the Eastern Brass & Copper Co., New York.

Joining of aluminum by soldering presented a problem because of the necessity for breaking up the tenacious oxide film that forms on aluminum. An ultra-high-frequency soldering gun that breaks up this oxide layer by sound waves was developed by Mullard Electronic Products, London. A new lead-free aluminum solder melting at 400° F. and flowing at 450° F., called Brazalloy No. 37, for use with Brazalloy AS No. 37 Flux, was developed for soldering all types of aluminum but 24ST alloy. Welding by the shielded-inert-gas metal-arc process, called sigma welding, employed a consumable wire electrode and permitted higher current densities (20 times carbon arc, double heliarc), deep penetration, narrow weld, and heat-affected area and produced less distortion in welded parts.

WORLD REVIEW [6]

World production of primary aluminum ingot in 1951 was 1,790,000 tons (partly estimated), a 20-percent increase over 1950 (revised data) and 2¼ times the post-World War II low year in 1946. North American producers in the United States and Canada dominated primary production, supplying 65 percent of the world total. Europe, exclusive of the U. S. S. R. and satellite countries, produced 20 percent, Asia 2.5 percent, and Russia and its satellites 12.5 percent (estimated). Every aluminum-producing country except the United Kingdom increased output in 1951. Brazil, the only new producer, was obtaining aluminum from a reactivated plant that had been idle since 1946. The United States, with the largest tonnage gain (107,300 tons), had a small percentage increase, 16.5 percent, when compared with Western European producers. Western Germany increased production by 166 percent, France 50 percent, Italy 34 percent, Austria 47 percent, and Switzerland 25 percent. In the Far East, Japan was the only large producer and increased output 49 percent over 1950. By continental areas, North America showed a gain of 15 percent, Europe (excluding U. S. S. R. and satellites) 45 percent, and Asia 44 percent over 1950. Despite the large increase in primary aluminum produced in 1951, construction of additional facilities was underway in Canada, United States, Brazil, Norway, Spain, Western Germany, Sweden, Yugoslavia, Hungary, U. S. S. R., and Taiwan. A new plant was under construction in Tasmania, Australia. Gold Coast (Africa), Venezuela, Borneo, and New Guinea were being studied as possible future sites for aluminum smelters.

[2] Revised figure.
[3] Estimated.
[4] April to June, inclusive.

Australia.—Australia's first primary aluminum plant, being constructed at Bell Bay, Tasmania, was expected to reach the production stage by late 1953 or early 1954. The annual capacity of this plant was rated at 13,000 metric tons of aluminum ingot. Reports on the construction progress disclosed that 95 percent of the steel for buildings and stores and 75 percent of the plant and equipment had been ordered. Japanese steel was imported to expedite construction. Technical assistance on the layout of the works and the design of specialized equipment was supplied by British Aluminum Co., Ltd.

Austria.—Aluminum production in Austria reached a postwar high of 26,380 tons. Austria had production facilities to produce over 50,000 annual tons, as shown by the peak August production of 4,192 tons, but the power supply was not adequate to supply these facilities. The major part of the production—about 20,000 tons—was obtained from the Ranshofen works and the remainder from Lend (Salzburg). A new 6,000-ton-per-year addition to the Lend plant was completed and put in operation in October. This plant produced its own power and would not be affected by power shortages. The power supply, which showed a marked increase in 1951, was expected to show further improvement in 1952. New power stations went into operation, and the new Limberg reservoir was completed. Completion of the Kapiun hydroelectric plant, expected in 1952, would raise the production of the Ranshofen plant. It was reported that producers were unable to accept all foreign orders for virgin metal, even though offers up to $700 a ton exceeded world market levels.

An aluminum semifabrication plant (extrusions, sheet, wire, etc.) went into operation in the summer of 1951 and had manufactured some 9,000 tons of aluminum shapes by the end of the year. This

Digitized by Google

plant was being expanded to produce a number of new aluminum-alloy semifabricated materials.

Brazil.—In 1951 Brazil became, for the second time, the only South American producer of primary aluminum. The aluminum plant at Ouro Prêto, Minas Geraes, began operating in October and was being run by Electroquimica Brasileira. This plant was constructed during World War II and produced 480 tons of metal in 1945 but closed early in 1946. The annual capacity of the smelter was between 2,000 and 3,000 tons. Bauxite was obtained from nearby deposits; power was supplied from company-owned hydroelectric plants and mineral pitch by the National Steelworks at Volta Redonda. Other raw materials, such as petroleum coke, caustic soda, fuel oil, and cryolite, were imported. The majority of the company stock was indirectly held by Aluminum, Ltd., through its subsidiary Aluminio de Brazil. The Companhia Brasileira de Alumino started construction of a 7,000-ton-per-year-capacity plant in São Paulo. It was planned to purchase equipment in Italy and Western Germany. The two facilities were to have capacity to supply most of Brazil's demand for aluminum.

Canada.—Production of primary aluminum in Canada increased 13 percent over 1950 to 405,600 tons. Four reduction plants were in operation, all in Quebec Province, at Arvida, Isle Maligne, Shawinigan Falls, and Beauharnois. Aluminum production was lower than anticipated because of subnormal water conditions during the fall months, causing a partial shutdown of the potlines at Arvida and Shawinigan Falls. A strike at the Shawinigan Falls plant also depressed production, however, company officials stated that because of low water conditions the strike was of comparatively little significance. The Beauharnois works, closed since the end of the war, was reopened, and an expansion of the Isle Maligne was completed during the second quarter of 1951.

Shipments of aluminum in all forms, according to the 1951 Annual Report of Aluminium, Ltd., totaled 434,000 tons. The distribution of aluminum in ingot form was 181,600 tons to the United Kingdom, 93,700 tons to the United States, 78,500 tons to Canada, and 48,900 tons to other countries. Shipments to the United States included 4,000 tons of ingot diverted from the United Kingdom under a trade agreement which called for a total delivery of 10,000 tons over a 5-month period beginning in November. The decline from 1950 of 53,800 tons in shipments to the United States was due in large part to contracts with the United Kingdom under which Canadian commitments to that country were increased. In addition, Canadian consumption increased 18,500 tons and shipments to other countries 11,100 tons.

The Canadian aluminum industry was conducting two major expansion programs, one in the Province of Quebec and the second in the Province of British Columbia. The program in Quebec was largely one of increasing hydroelectric power-generating capacity to permit full utilization of the existing aluminum-reduction capacity in Quebec and to supply additional power for a second expansion at the Isle Maligne plant. The Quebec smelters had not operated at rated capacity since World War II, when large amounts of purchased power were diverted, by Government orders, from less essential uses. Two new power plants on the Peribonka River, known as Chute du

Digitized by Google

Diable and Chute-a-la-Savane, with a firm generating capacity totaling 410,000 hp., were scheduled for completion in late 1952 or early 1953. The expansion program in British Columbia called for construction of a reduction smelter and power facilities, with alumina to be supplied from a plant in Jamaica. The project included construction of a dam across the Nechako River to seal the eastern exit of the watershed; a 10-mile tunnel through the Coastal Range to the Kemano powerhouse built a quarter of a mile inside the Coastal Range's Portal Mountain, with an initial capacity of 450,000 hp. and a potential capacity of 1,650,000 hp.; and a 50-mile transmission system to Kitimat, where the reduction plant was to be located. Harbor and dock facilities for rapid handling of alumina cargos from Jamaica were to be constructed at Kitimat, which is on tidewater at the head of the Douglas Channel. The hydro potential of the British Columbia project was rated capable of generating enough power to produce 500,000 tons of aluminum annually. The development was planned as a three-stage expansion. The first stage was to provide power and reduction facilities for 83,000 tons of aluminum annually; in the second stage a total of 250,000 tons was to be produced annually and in the third stage 500,000 tons. Initial production was planned for mid-1954. The completion dates of latter stages was to depend on the world demand for aluminum. Construction of the dam, tunnel, powerhouse site, smelter site, and dock facilities was in progress during 1951.

France.—In 1951 France, the largest producer in Western Europe, produced 91,080 tons of aluminum, the highest annual production ever attained and a 50-percent increase over 1950. Of the total, the Compagnie de Produits Chimiques et Électrométallurgiques Alais, Froges et Camargue (Pechiney) produced 82 percent and the Société d'Électrochimie, d'Électrométallurgie et des Ocieries Électriques d'Ugine (Ugine) the remainder. All aluminum in France was marketed through L'Aluminium Français. The record production was possible because of modernization of plant facilities and an improved electrical power supply. Despite the increased production, exports were banned except to fulfill previous commitments to the Netherlands and South America and that which went to Belgium in exchange for copper. Exports were approximately 8,000 tons, less than half of 1950 exports. The consumption pattern in France showed the automobile industries as the major consumer (approximately 30 percent) followed by the electrical industries (approximately 24 percent). The domestic price of primary aluminum, fixed by the French Government, was raised from 161,000 francs per ton (21 cents per pound) to 181,000 francs (23.5 cents per pound) in October. A premium of 19,000 francs per ton (2.5 cents per pound) was added in December to cover higher power costs, part of which was supplied from thermal power plants, during the winter. Export prices were not controlled.

Germany.—Aluminum production in West Germany was more than 2½ times that of 1950, totaling 74,136 tons in 1951. The combined capacity of the three plants operating in 1951 was about 95,000 annual tons, but power shortages prevented capacity operation. The ceilings placed on aluminum production by the allied powers were removed, and previous plans for dismantling aluminum facilities were abandoned. The second of three potlines at the Luenen (West-

Digitized by Google

phalia) works was opened in March 1951; the first line had resumed operation in December of 1950, and total operation of the plant was planned in 1952. The third line of the Toeging (Bavaria) plant, which had been dismantled, was being rebuilt. The Erftwerke (Grevenbroich) hyrdoelectric plant and aluminum plant (near Cologne) were being reconstructed, and operation of 11,000 tons of annual capacity was anticipated for early 1953. Construction of new power facilities on the German-Austrian border, to be owned by the Austrian-Bavarian Power Co., was begun in March, mainly to supply power to Toeging in Western Germany and the Ranshofen plant in Austria. A rolling mill near Ranshofen opened in 1951 and produced about 10,000 tons of aluminum sheet and shapes. The price of aluminum from January to April was 2.08 DM per kilogram, equal to approximately 22.4 cents per pound.

Statistical data on aluminum production in East Germany (Soviet) were not available and it was doubtful that appreciable amounts of primary aluminum were produced in this area. A small potline at Bittlefeld (Saxony) was reported in operation to supply pure aluminum for upgrading reclaimed metal.

Hungary.—Hungary was the only Soviet satellite country known to produce primary aluminum. Under the Soviet blueprint for expansion of mineral and metal production in the satellite countries, Hungary was to expand aluminum production. A precise evaluation of the progress made toward realization of these plans was impossible because of the lack of reliable statistical data.

India.—Two companies, the Indian Aluminium Co., Ltd., an Indo-Canadian company, and the Aluminium Corp. of India, an all-Indian company, supplied all of the primary production of India. Plans for expanding facilities to supply India's total requirements were being investigated by the producers and by the Government. The Government of India Planning Commission recommended expansion of existing facilities in preference to establishing new plants. The maximum capacity to which the existing plants could be expanded, based on the availability of electrical power, was estimated at about 5,000 annual tons. A new plant of 15,000 tons annual capacity was tentatively suggested for Hirakud in Orissa, using hydroelectric power from a dam and generating facilities yet to be installed. Exports of all aluminum products were prohibited, except for aluminum utensils, which India had exported to South Asia, the Middle East, and East Africa for a number of years.

Italy.—Production of primary aluminum in Italy in 1951 was at an alltime high. The total annual capacity of the country was approximately 57,000 tons, held by three companies: Societa Allumino Veneto per Azioni (S. A. V. A.), with a plant at Porto Marghera; Industria Nozionale Allumina (I. N. A.), incorporated in the Montecatini enterprises in 1951 with plants at Mori and Belzano; and Societa dell'Allumino Italiana (S. A. I.), with a small plant at Borgofrance d'Ivria. The capacity was distributed approximately as follows: I. N. A., 60 percent; S. A. V. A., 30 percent; and S. A. I., 10 percent. S. A. V. A. also produced "superpurity" aluminum of 99.99-percent purity. New hydroelectric facilities on the Travignolo (Province of Trento), with a yearly output of 100 million kw.-hrs., were under construction for improved power supply at Porto Marghera.

Digitized by Google

The official price of aluminum (99.0 percent purity) was raised from 340 lire to 365 lire per kilogram (24.7 cents to 26.5 cents per pound) in March. The import duty on aluminum was 28 percent *ad valorem*.

Japan.—Production of primary aluminum in Japan in 1951 was about 36,780 tons, an increase of about 49 percent over 1950. The increased production came from reactivation of production facilities that had been idle since World War II. The 1951 production was about one-third of the rated primary capacity of Japan in 1942. Primary aluminum was produced by three companies, Japan Light Metals (Nippon Kerkinzoku KK), Showa Electrical Industries (Showa Denko KK), and Nisshin Chemical (Nisshin Kaguku KK). Exports of primary pig and ingot aluminum, which totaled more than production in 1950, declined from 14,844 tons to 4,546 in 1951. The decrease in exports was caused by increased consumption in Japan and the premium price of Japanese aluminum. In January the price of 99.5-percent aluminum was increased to 210,000 yen per ton (26.5 cents per pound) and in September to 235,000 to 240,000 yen per ton (30 cents per pound).

New Guinea.—A prospective aluminum reduction development in New Guinea that would use waterpower from the Owen Stanley Range was being investigated by the Australian Government and the British Aluminium Co., Ltd. A preliminary survey revealed that 15 million kw. of power could easily be developed and that 100 million kw. would eventually be available.

Norway.—Norwegian production of primary aluminum reached an alltime high of 51,240 tons in 1951, marking the sixth successive year of increasing production. The increase over 1950 was due largely to the first full year's operation of the second potline of the reduction plant at Aardal.

Although Norway's aluminum requirements were estimated at 10,000 to 15,000 tons per year, less than one-third of the production, work on a new 40,000-ton-per-year-capacity smelter at Sunndalsora was in progress. According to plan, the plant was to consist of an anode paste plant, 2 potlines of 132 cells each, a rectifier station, and facilities for producing notched bars, wire bars, rolling slabs, billets, and alloy ingots. Space was reserved for an additional 34 cells, which would increase the capacity to 50,000 tons a year. Alumina was to be imported under a long-term contract with Aluminium Union, Ltd., of Canada, which provided for delivery of 800,000 tons of oxide. The new works was to cost an estimated $35,000,000, $24,000,000 of which the Norwegian Government was to receive in the form of an ECA loan. The ECA loan was to be repaid by deliveries of aluminum over a 10-year period starting in 1955. The State-owned Aura power station was being expanded to a generating capacity of 250,000 kw, about half of which was for the Sunndalsora plant. Initial production was anticipated in 1954.[7]

Exports of aluminum were 41,881 tons in 1951 as compared to 40,351 tons in 1950 and were expected to be somewhat lower in 1952 because of increased domestic consumption, chiefly in electrical power transmission. A/S Aardal og Sunndal Verk was reported to be

[7] Light Metals, New Aluminum Smelter for Norway: Vol. 15, No. 166, January 1952, pp. 14, 15

Digitized by Google

receiving about 4,000 kroner per ton (25.4 cents per pound) for aluminum at the end of 1951.

Spain.—The production of aluminum in Spain increased 65 percent over 1950 to 3,847 tons. The added production was obtained by expanding operations at the reduction plant of Empresa Nacional de Alumino S. A. at Valladolid. This plant, opened in November of 1949, had a planned capacity of 5,000 annual tons and produced about 2,500 tons in 1951. Consumption (fabrication) capacity exceeded the supply of ingot material and prices were much higher than in other Western European countries. Duties on imports varied from 19 cents per pound for ingot to $1.19 for foil sheets and coils less than 0.5 mm. thick. The high duties, exchange difficulties, and low domestic production depressed fabrication and consumption.

Sweden.—Sweden increased its production of aluminum and aluminum alloys from 4,038 tons in 1950 to 6,600 in 1951. Swedish consumption was estimated at 16,000 to 17,000 tons annually, and plans were underway for increasing the production capacity to 10,000 tons per year by 1954. The major part of Sweden's imports was from Norway.

Switzerland.—An increase of almost 5,000 tons in 1951 production over 1950 was due chiefly to greater demand and higher prices for aluminum products. Electrical power was purchased from noncompany sources to maintain maximum production during the winter months, when company-owned hydropower production decreased. Imports of virgin aluminum increased from 2,745 tons in 1950 to 5,120 in 1951. The domestic price for pure aluminum pig, which was 2 francs per kilogram (21.2 cents per pound) during 1950, was raised to 2.3 francs per kilogram (24.3 cents per pound) in January 1951. The average price of exported aluminum pig was 258 francs per 100 kilograms (26.8 cents per pound) in November 1951 compared with 206 francs (21.5 cents) in November 1950.

Taiwan (Formosa).—Production of 2,598 tons of aluminum by the Taiwan Aluminum Corp., the only producer in 1951, marked a postwar peak but fell short of the 3,300-ton goal. Production was limited by a shortage of raw materials and replacement equipment and by insufficient power for continuous operation. The company made plans to rehabilitate additional units of the reduction plant, which had an annual capacity of 15,000 tons under Japanese management, and for installation of a foil mill to supply the island's tea and cigarette industries.

United Kingdom.—Production of virgin aluminum in the United Kingdom declined about 6 percent from 1950 because of inability to maintain an adequate labor force for the Highland Reduction Works. During the post-World War II years United Kingdom production had been relatively constant, and no large increase in domestic production was feasible because of the limited power resources of the British Isles. The domestic primary aluminum capacity of 30,000 annual tons supplied about one-sixth of United Kingdom requirements, and provisions for obtaining the major part of its aluminum requirements were made through long-term contracts with Canada. The United Kingdom was actively investigating new sites that might offer promise of economical aluminum production in Gold Coast (Africa) and Borneo.

Digitized by Google

Throughout 1951 the aluminum picture in the United Kingdom was similar to that in the United States; demand was ahead of supply, consumption of primary metal was controlled by the Government, ceiling price orders were necessary to control the price of secondary metal. The price of virgin aluminum was raised from 120 to 124 pounds per long ton (15–15.5 cents per pound) in January 1951, where it remained throughout the year.

Yugoslavia.—The aluminum-reduction plant at Lozovak, Dalmatia, was being expanded during 1951. The reported capacity of this plant was 3,000 tons a year before expansion and the capacity was to be raised to 7,000 tons. Construction continued on a plant partly built by the Germans during World War II at Strnisce, Slovenia. The first reduction building, reported to be the largest industrial building in Yugoslavia, had been completed, and electrolytic cells were being installed. The yearly capacity of the first potline was to be 15,000 tons a year, and initial operation was planned for 1954.

Antimony

By Abbott Renick and E. Virginia Wright

GENERAL SUMMARY

THE 1951 world output of antimony—64,000 metric tons—was 20,000 tons higher than in 1950 and exceeded the 1942–46 average (40,860 tons) by 57 percent.

Increases in the domestic primary antimony industry were as follows: Mine output, 39 percent; smelter production of metal, oxide, and sulfide, 29 percent; consumption of primary antimony, 13 percent; and industry stocks, 6 percent. Imports of antimony contained in ore, of metal, and of oxide and needle antimony increased 2 percent. Secondary production was 10 percent above the 1950 output. Quoted prices for antimony, RMM Brand, in cases, New York City, varied between a low of 33.78 and high of 51.85 cents per pound. According to the American Metal Market, average price for the metal during 1951 was 44.17 cents (New York equivalent) per pound compared with 29.41 cents in 1950.

The "new supply" of primary antimony in 1951, in terms of recoverable metal, was 20,430 short tons. A breakdown of this supply shows that domestic antimony ores contributed 3,194 tons,[1] domestic

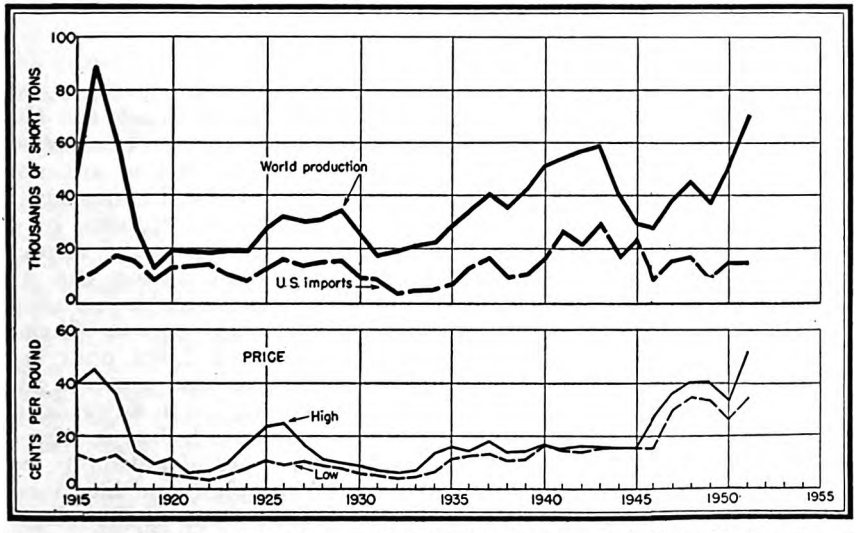

FIGURE 1.—World production, United States imports and New York price of antimony, 1915–51.

[1] In terms of recoverable metal content calculated at 92 percent of mine and mill production.

Digitized by Google

and foreign lead-silver ores 2,356 tons, and imports 14,880 tons. The contained antimony imported for consumption arrived as follows: Ore and concentrates (in terms of recoverable metal), 10,953 tons; metal, 2,231; needle, 4; and antimony oxide, 1,692. The supply from secondary sources was 23,943 short tons.

Total consumption of antimony in the United States in 1951 was 43,818 short tons, comprising 17,519 tons of primary, 2,356 tons of antimony contained in domestic and foreign silver and lead ores consumed by primary lead refineries in the manufacture of antimonial lead, and 23,943 tons of secondary antimony.

Government Regulations.—As a result of the defense program, together with the continued high level of civilian demand, the Government moved to conserve the supply of antimony. The National Production Authority placed limitations on inventories of antimony and materials containing antimony, other than ores and concentrates. Effective February 16, 1951, Order M–39 limited acceptance of deliveries to the smallest quantity of material reasonably required to meet the current scheduled rate of operations during the next succeeding 60-day period, or in excess of a practicable minimum working inventory. Order M–39 provided that any person who produced, consumed, imported, shipped, or received 2,000 pounds or more of antimony contained in antimony ores and concentrates, antimony metal, antimony oxide, or antimony sulfide in any calendar month or who, on the last day of any calendar month, had in his possession or under his control 2,000 pounds or more of antimony contained in these forms and materials, should complete and file Bureau of Mines report form 6–1016–M. (*See* Price section of this chapter for price regulations.)

DOMESTIC PRODUCTION

MINE PRODUCTION

During 1951 production (shipments) of antimony ores and concentrates totaled 9,401 short tons containing 3,472 tons of antimony, of which 3,194 tons was estimated as recoverable. (For recovery of antimony from silver and lead ores, see Smelter Production section of this chapter.) Compared with 1950, the 1951 output from antimony ores and concentrates increased 39 percent.

Alaska.—Earl Pilgrim operated the Stampede mine in the Kantishna district, where a new ore discovery was made during the year; Alamco, Inc., conducted the Sawtooth Mining Co. operations and also worked the Tok district property of Sam Gamblin.

Idaho.—Bradley Mining Co., the principal producer of antimony in the United States, produced 8,120 short tons of concentrate containing 2,851 tons of antimony. Improvements and plant additions included moving the crushing plant feed bins to a new location.

Hermada Mining Co. operated its mine in Elmore County, and the Sunshine Mining Co., Shoshone County, recovered considerable antimony from silver-lead ores.

Nevada.—G. A. Peterson operated the New Potosi mine in Mineral County, and John Heizer operated an antimony mine in Pershing County.

Washington.—Gray, Oberbillig, and Person (G. O. P. Antimony, Inc.) operated the Lucky Knock and Bales Mines in Okanogan County.

TABLE 2.—Antimony-bearing ores and concentrates produced (shipments) in the United States,[1] 1942–46 (average) and 1947–51, in short tons

Year	Gross weight	Antimony content		Year	Gross weight	Antimony content

[1] Includes Alaska.

SMELTER PRODUCTION

Primary.—Antimony smelters in the United States produced metal, oxide, sulfide, and residues containing a total of 12,228 short tons of antimony from domestic and foreign ores in 1951, a 29-percent increase over 1950. Approximately 61 percent of the output in 1951 (about 65 percent in 1950) was in the form of oxide.

In 1951, 2,356 short tons of antimony (17 percent less than in 1950) was recovered in antimonial lead produced by domestic primary lead refineries from silver and lead ores. (*See* Lead chapter of this volume for detailed discussion of antimonial lead production.)

Secondary.—Antimony produced at secondary metal plants was 21,883 short tons, plus 2,060 tons recovered in antimonial lead from scrap at primary lead refineries, for a total production of 23,943 short tons, a 10-percent increase over the 21,862 tons produced in 1950. (*See* Secondary Metals—Nonferrous chapter of this volume for detailed review.)

1949	8,099	41,402	1,214	396	1,775	3,385	8.2	18,061
1950	9,471	61,912	2,253	597	1,654	4,504	7.3	21,862
1951	[5] 12,228	65,309	1,663	693	2,060	4,416	6.8	23,943

[1] Includes primary residues and small quantity of antimony ore.
[2] Includes foreign base bullion and small quantity of foreign antimony ore.
[3] Includes antimony content of antimonial lead produced at primary lead refineries from scrap.
[4] Data not available.
[5] Includes primary antimony residues.

CONSUMPTION AND USES

The total consumption of antimony in the United States in 1951 was 43,818 short tons, an increase of 9 percent over 1950. Primary antimony used was 17,519 short tons (15,494 tons in 1950); the antimony content of lead-silver ores consumed in the manufacture of antimonial lead by primary lead refineries was 2,356 short tons (2,850 in 1950), and the alloy content of secondary antimony was 23,943 short tons (21,862 tons in 1950).

Consumption of primary antimony in the manufacture of finished products exceeded that for 1950 by 13 percent, with use in metallic products decreasing 19 percent and in nonmetallic products increasing 66 percent. (See table 4.) Antimony recovered and simultaneously consumed in antimonial lead was 17 percent less than in 1950. Consumption of secondary antimony was chiefly in metallic products and increased 10 percent over the amount consumed in 1950.

Progress was announced in 1951 in the development of a marine paint to eliminate the hazard of fire. "Erifon," a flame retardant, was described as essentially a solution of titanium tetrachloride and antimony chloride in water.[2]

A new fluorescent lamp with a double cathode in place of the standard single cathode was reported to have exceedingly long life—up to 10,000 hours under rigorous conditions. The addition of antimony 51 to the phosphor powder was said to be an effective activator, which also reduced the tendency toward tube discoloration of standard lamps.[3]

TABLE 4.—Industrial consumption of primary antimony, 1947–51, in short tons[1]

Product	1947	1948	1949	1950[2]	1951[2]
Metal products:					
Ammunition	24	21	6	9	4
Antimonial lead	[3] 6,172	[3] 6,024	[3] 4,737	[3] 4,912	2,431
Battery metal	(4)	(4)	(4)	(4)	2,774
Bearing metal and bearings	2,056	1,803	873	3,256	1,308
Cable covering	61	62	172	72	95
Castings	129	81	49	126	79
Collapsible tubes and foils	77	31	14	23	18
Galvanizing					11
Sheet and pipe	225	195	306	300	180
Solder	132	145	155	162	123
Type metal	1,216	1,019	587	766	709
Other	(4)	(4)	(4)	(4)	41
Total metal products	10,092	9,381	6,899	9,626	7,773
Nonmetal products:					
Ammunition primers	16	6	9	9	18
Antimony sulfide (precipitated)					[5] 68
Fireworks	(6)	(6)	(6)	(6)	20
Flameproof coatings and compounds	(6)	(6)	(6)	(6)	463
Flameproofed textiles	205	388	273	369	2,590
Frits and ceramic enamels	1,754	1,561	1,155	1,462	1,476
Glass and pottery	421	352	296	579	570
Matches	23	37	28	56	31
Paint and lacquers	1,324	1,288	874	267	962
Pigments	(6)	(6)	(6)	(6)	705
Plastics	[7] 156	228	498	737	747
Rubber products	39	41	55	103	19
Toy caps	(6)	(6)	(6)	(6)	24
Other [8]	2,617	2,173	1,443	2,286	2,053
Total nonmetal products	6,555	6,074	4,631	5,868	9,746
Grand total	16,647	15,455	11,530	15,494	17,519

[1] Data for 1947–48 compiled from monthly applications filed with the Office of Materials Distribution, U. S. Department of Commerce (formerly with War Production Board and Civilian Production Administration).
[2] Data 1950–51 include certain intermediate smelting losses which have been deducted for earlier years.
[3] Includes alloys, battery metal, and other.
[4] Included with "Antimonial lead."
[5] Not reported as an end use in prior years.
[6] Included with "Other nonmetal products."
[7] Consumption April through December 1947; January-March included with "Other."
[8] Also includes antimony trichloride and sodium antimonate to avoid disclosure of individual company operations.

STOCKS

At the close of 1951 industry stocks of antimony were 6 percent higher than the 8,888 tons reported at the end of 1950. Mine stocks at the beginning and end of 1951 were 626 and 479 tons, respectively. Other industry stocks were 8,262 tons at the end of 1950 and 8,934 tons on December 31, 1951.

TABLE 5.—Industry stocks of antimony in the United States at end of year, 1950–51, in short tons of contained antimony

Raw material	December 31, 1950			December 31, 1951		
	Mine	Other[1]	Total[1]	Mine	Other	Total
Ore and concentrates	626	2,630	3,256	479	3,257	3,736
Metallic antimony		2,240	2,240		2,574	2,574
Antimony oxide		2,662	2,662		2,672	2,672
Antimony sulfide (needle)		184	184		109	109
Primary antimony residues and slag[2]		546	546		322	322
Total	626	8,262	8,888	479	8,934	9,413

[1] Revised.

PRICES

The price of antimony metal in bulk, f. o. b. Laredo, Texas, averaged 42.35 cents per pound; ranging from a low of 32.00 to a high of 50.00 cents, in 1951. The average New York price was 1.82 cents a pound higher than the average Laredo quotation being 44.17 cents a pound for 1951, according to American Metal Market averages for the year.

According to E&MJ Metal and Mineral Markets, opening and subsequent changes in nominal quotations for antimony ore during 1951, per unit (20 pounds) of antimony contained, were as follows:

	50–55 percent	*58–60 percent*	*60–65 percent*
Jan. 4, 1951	$4. 50–$4. 60	$4. 75–$4. 85	$5. 25–$5. 35
Jan. 25, 1951	4. 75– 5. 00	5. 00– 5. 25	6. 25– 6. 50
Mar. 1, 1951	5. 25– 5. 50	5. 50– 5. 75	6. 50– 7. 50
May 3, 1951	5. 50– 5. 75	5. 75– 6. 25	7. 00– 7. 50
June 28, 1951	6. 00– 6. 25	6. 50– 7. 00	7. 00– 7. 50
Sept. 13, 1951	6. 25– 6. 50	6. 75– 7. 00	7. 25– 7. 50
Nov. 1, 1951	6. 25– 6. 50	6. 75– 7. 00	7. 75– 8. 25
Dec. 6, 1951	5. 50– 6. 00	5. 75– 6. 25	7. 25– 7. 50
Dec. 20, 1951	5. 50– 5. 75	5. 75– 6. 00	6. 75– 7. 00

Effective November 21, 1951, the Office of Price Stabilization issued Ceiling Price Regulation 96, covering sales of antimony metal, antimony oxide, and sodium antimonate, including any sold by an importer or exporter. In general, the regulation set basic ceiling prices for carlots, with adjustments to reflect certain transportation charges and with specified differentials for less than carlots and for special packing.

Ceiling prices for carlots of antimony metal were set at 49½ cents, 50 cents and 50½ cents per pound, f. o. b. shipping point, depending on grade.

A ceiling price for delivered carlots of antimony oxide in bags was set at 48 cents a pound; for sodium antimonate the price was set at 42 cents. Effective December 13, 1951, the OPS issued General Overriding Regulation 9, Amendment 10. This exempted from price control all sales of domestic antimony ores and concentrates.

FOREIGN TRADE [4]

Imports.—Antimony in ore, imported for consumption, increased 22 percent in 1951. The average grade of ore was about 44 percent. Antimony metal imports declined 52 percent under the 1950 imports of metal; imports of antimony as needle continued negligible. Imports of antimony ore and concentrates were principally from Bolivia, Mexico, Union of South Africa and Canada. Imports of metal were chiefly from Mexico, Belgium-Luxembourg, Yugoslavia, France, United Kingdom, and Peru.

The 1951 imports of antimony oxide, the largest ever recorded, exceeded those of 1950 by 76 percent. The bulk of it came from the United Kingdom and Belgium-Luxembourg.

TABLE 6.—Antimony imported for consumption in the United States, 1947–51 [1]

[U. S. Department of Commerce]

Year	Antimony ore			Antimony needle		Antimony metal		Type metal and antimonial lead [2] (short tons)	Antimony oxide	
	Short tons (gross weight)	Antimony content		Short tons (gross weight)	Value	Short tons	Value		Short tons (gross weight)	Value
		Short tons	Value							
1947	28,471	9,257	$2,672,249	17	$7,914	5,879	$3,487,126	187	----------	----------
1948	41,610	13,464	4,312,431	533	314,809	3,201	2,022,676	1,569	----------	----------
1949	17,855	7,473	2,488,271	81	42,537	1,853	1,242,582	654	56	$27,290
1950	22,307	9,746	1,850,162	19	8,895	4,632	2,204,091	[3] 1,936	1,160	428,386
1951	27,354	11,905	4,621,437	6	5,936	2,231	1,780,576	676	2,039	1,525,016

[1] Does not include antimony contained in lead-silver ore.
[2] Estimated antimony content; for gross weight and value, see Lead chapter of this volume.
[3] Revised figure.

Exports.—Exports in 1951 (gross weight) of antimony ore and concentrates were 5 short tons valued at $5,072; and of metal and alloys, 163 tons valued at $146,051. During 1950 exports (gross weight) included 6 short tons of antimony ore and concentrates valued at $865 and 148 tons of metal and alloys valued at $86,496. Reexports of ore in 1951 were 128 tons valued at $30,943, and of regulus or metal, needle, scrap, and alloys, 6 tons valued at $6,050.

[4] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

TECHNOLOGY

Smelting antimony in Yugoslavia was the subject of an article, in which short descriptions of three antimony smelters were given, and the development and modernization were described in more detail.[5]

Articles were published in 1951 on the electrodeposition of ductile and malleable antimony [6] and a procedure for the photoelectric spot analysis of antimony.[7]

In a 1951 paper on the gold-antimony mineralization in the Yellow Pine District, Idaho, resemblance of the early gold mineralization to that at Rocky Bar and Boise Basin was noted and the belief expressed that both the gold and antimony mineralization occurred in the early Tertiary epoch.[8]

Several United States patents relative to antimony were issued during 1951.[9]

WORLD REVIEW

Australia.—The smelter of O. T. Lempriere & Co., Ltd., at Sydney, has been designed to treat ore of an average grade of not less than 50 percent; on material of this grade the annual capacity is about 1,200 short tons of metal.[11]

Austria.—The Schlaining mine (Soviet Zone) produced 6,066 metric tons of ore in the first 9 months of 1950.[12]

The Bleiberger Bergweksunion started operating an antimony-dressing plant at its Rabant mine in 1951.[13]

Algeria.—In 1951 Algerian production of antimony ore was 4,829 metric tons with a content of 1,462 metric tons antimony.[14]

Canada.—Sole producer in Canada has been the Consolidated Mining, Smelting & Power Co., Ltd., which recovers the metal as antimonial lead alloy from residues of lead refining.[15]

France.—Antimony smelter production in France in 1951 was 1,521 metric tons, representing an increase of 24 percent over 1950.[16]

Greece.—Deposits of antimony occur throughout Thrace and Macedonia in Greece. The only producing company in 1951 was Hellenic Mining Co., on the island of Chios. Most of the ore mined was stored at the mine for milling after construction of a proposed flotation plant. The Lakhanas mine in the Province of Serres received an Economic Cooperation Administration loan of $24,932 in foreign exchange credits and 311 million drachmas for local expenditures

Italy.—Azienda Minerali Metallici Italiani (State control 100 percent) mines antimony-ore deposits and operates an antimony smelter at Su Suergiu in Sardinia and at Manciano in Tuscany. Prewar output was 1,000 metric tons annually.[17]

Peru.—Interest in antimony properties increased. Several foreign and domestic companies were prospecting near Luliaca in Southern Peru, and near Canta.[18]

Turkey.—The Eti Bank and the Mining Research and Exploration Institute (MTA) estimated antimony-ore (50-percent) reserves at 40,000 metric tons. The projected output of antimony for 1952–53 is 5,000 metric tons.[19]

United Kingdom.—The consumption of antimony metal and compounds (in terms of antimony metal) in 1951 was reported as follows:[20]

	Long tons
Batteries	1,206
Other antimonial lead	778
Bearings	463
Oxide and compounds	3,382
Miscellaneous uses	447
Total, all trades	6,276

The above figures exclude the consumption of antimony in scrap, which was as follows:

	Long tons
Antimonial lead	2,800
All other purposes	1,056
Total consumption in scrap	3,856

Union of South Africa.—There has been a notable expansion of antimony production since 1938. Production in 1951 amounted to 15,858 metric tons. The Union is now the largest producer in the world.

Production is confined to the Murchison Range in the North-Eastern Transvaal, where a long and narrow belt of mineralised schistose rocks occurs in granite and gneiss. The feature of this belt is a mineralised zone, "the Antimony Line", which is characterised by antimony minerals. The most important of these is stibnite, but berthierite, tetrahedrite, corynite, chalcostibite and various oxides of antimony occur in minor quantities.

Although mineralisation occurs throughout the greater part of this line, only at certain localities have antimonial deposits of commercial value been found. These are mineralised lens-like irregular bodies, varying in width from a few inches to 20 ft.

All the antimony minerals contain some gold and silver and it was for their gold content that the reefs were originally worked. There have, in fact, been three distinct phases in the mining of Murchison ores. Originally the antimonial ores were worked exclusively for gold, reduction being complicated by the refractory nature of the ores. Then antimony was exploited as a byproduct and now it might be said that antimony has become the main product and gold the byproduct.[21]

[5] Excludes Soviet Zone, data for which are not available, but estimates for which are included in the totals.
[6] Data not available; estimate by the chapter author included in total.
[7] Estimate.
[8] Including Spanish Morocco.
[9] Fiscal year ended Mar. 20 of year following that stated.
[10] Included in Spain.

Yugoslavia.—Antimony deposits at Zajaca were estimated in 1951 to contain 150,000 metric tons.[22]

The main deposits are in the Zajaca Bazen (Zajaca Basin) and the well known Krupanj properties are part of this group. The town of Loznica in Serbia is nearby. There is an antimony smelter at Zajaca, and an ore dressing plant here is treating antimony ores by the flotation process; Yugoslavia is the first European country to do this. There are a number of small flotation plants in the neighbourhood but a big one is being constructed at Zajaca; the small plants will not be put out of use when it is completed. Efforts are being made throughout the country to find additional antimony deposits. The Krupanj plant was destroyed during the war. The capacity of the Zajaca undertaking (styled Rudnici i Topionice Antimona Zajaca) is 1,500 metric tons of metallic antimony yearly.[23]

Arsenic

By Abbott Renick

GENERAL SUMMARY

PRODUCTION of white arsenic in the United States increased 22 percent in 1951 over that in 1950 and exceeded the 1946–50 average (14,735 short tons) by 10 percent. Imports for consumption in 1951 decreased 2 percent. Producer stocks of white arsenic increased from 2,479 tons to 4,790 in the course of the year.

Of the total white arsenic available for United States consumption in 1951, domestic production (from domestic and foreign ores) constituted 53 percent and imports 47 percent. Apparent consumption was 1,839 tons less than supply.

Droughts in the cotton belts during the year reduced the requirements for pesticides, which are used by farmers as insecticides. Adequate stocks of the organic insecticides were available to reduce the requirements of lead arsenate and calcium arsenate.

The quotation for white arsenic was steady through the year at 6½ cents per pound.

[5] Conjectural.

DOMESTIC PRODUCTION

Reports from producers indicate that the output of crude and refined white arsenic in the United States totaled 16,190 tons in 1951, an increase of 2,917 tons over 1950.

Crude and refined white arsenic was produced in 1951 by the Anaconda Copper Mining Co., at Anaconda, Mont. (copper smelter); United States Smelting, Refining & Mining Co., at Midvale, Utah (lead smelter); and American Smelting & Refining Co., in plants at Tacoma, Wash. (copper smelter), and Murray, Utah (lead smelter). Arsenic metal was not produced during 1951.

[1] Excludes crude consumed in making refined. Includes crude white arsenic equivalent of compounds made directly from ores, flue dust, and speiss, as follows: 1942–46 (average), 239 tons; 1947, 97; 1948, 88; 1949, 26; 1950, none; 1951, none.

CONSUMPTION AND USES

During 1951 apparent consumption of white arsenic was 28,869 short tons, a 10 percent decline below 1950. The major portion of white arsenic produced is employed in manufacturing lead and calcium arsenate insecticides. Serious droughts in sections of the cotton area in 1951 minimized boll-weevil infestation. Ample supplies of lead arsenate and calcium arsenate were available during the year.

Arsenic is also consumed in glass manufacture, sheep dip, poisoned baits, pharmaceuticals, acid-resistant copper, and antimonial lead alloys. Sodium arsenate is used as a weed killer. Wolman salts or tanalite (25 percent sodium arsenate) is used as a wood preservative. Arsenical sprays have been employed since the end of the last century to protect growing tobacco.

TABLE 3.—Production of arsenical insecticides and consumption of arsenical wood preservatives in the United States, 1942–46 (average) and 1947–51

Year	Production of insecticides (short tons) [1]		Consumption of wood preservatives (pounds) [2]
	Lead arsenate (acid and basic)	Calcium arsenate (100 percent $Ca_3(AsO_4)_2$)	Wolman salts (25 percent sodium arsenate)

STOCKS

Producers' stocks of white arsenic at the end of 1951 were 4,790 short tons, a sharp increase from 2,479 at the close of 1950. Data are not available on stocks of calcium and lead arsenate held by producers.

PRICES

The carlot quotation for refined white arsenic held at 6½ cents per pound through 1951. The Metal Bulletin (London) quotation for metal opened in January 1951 at £425 and in the latter part of December was £500 per long ton. The London price of white arsenic, 99–100 percent, opened in January at £44¼–£47¼, and in the latter part of December was quoted at £55¼–£57¼.

FOREIGN TRADE [1]

Imports.—White arsenic imported totaled 14,518 short tons in 1951 compared with 14,774 tons in 1950, 4,696 tons in 1949, and an average of 12,366 tons in 1946–48. Of the tonnage imported in 1951, 75 percent came from Mexico, which has long been the principal foreign source. France supplied 13 percent.

Imports of metallic arsenic totaled 220,668 pounds, with United Kingdom supplying 59, Sweden 21, and Germany 19 percent.

Virtually all of the 1951 imports of arsenic sulfide originated in Belgium-Luxembourg; arsenical sheep dips came exclusively from United Kingdom.

Digitized by Google

Exports.—Producers of white arsenic reported no direct foreign sales in 1951. Exports of calcium arsenate increased 39 percent from those of 1950, whereas exports of lead arsenate decreased 40 percent. Mexico was the principal recipient of calcium arsenate, with Colombia, Nicaragua, Cuba, and others following in order. Their respective proportions of the total were 73, 18, 6, 2, and 1 percent. Cuba was the principal recipient of lead arsenate and, with Chile, received 86 percent of the total exported.

WORLD REVIEW

Canada.—Although arsenical ores are widely distributed in Canada, the production of arsenic is limited to a few localities where it is recovered as a byproduct in treatment of gold or silver-cobalt ores. About 1,202 tons of white arsenic was produced in 1951 compared with 397 in 1950. Domestic demand for refined white arsenic has shown a marked increase over the past several years. Canada's output of crude white arsenic continued to come from the O'Brien Gold Mines Co., and consolidated Beattie Mines, Ltd., in Cadillac and Duparquet Townships, Quebec.

United Kingdom.—The Metal Bulletin reported as follows: [1]

In contrast to earlier years, there was a growing demand for white arsenic during 1951 and with synthetic insecticides of the DDT group becoming increasingly difficult to produce as a result of sulphuric acid shortages a return to arsenical compounds was noted. Rising costs, notably in the price of coal, made for higher selling prices of foreign white in this country although attempts were made to give users the benefit of a stabilized quotation; however, leading suppliers were forced owing to limited availability to exclude sporadic business in favour of meeting regular consumers' needs, and even the latter were rationed in their figures with supplies virtually impossible to obtain in the open market. In the main, metal prices remained fairly steady although rising costs in general made for increases on occasion.

[1] Metal Bulletin (London), No. 3654, Dec. 28, 1951, p. 27.

Digitized by Google

Mexico.—Byproduct white arsenic was recovered by Cia. Metalurgica Peñoles, S. A. (subsidiary of American Metal Co.), at its Torreon, Coahuila, lead smelter. The American Smelting & Refining Co. produced white arsenic at its San Luis Potosi copper smelter.

Portugal.—Production of white arsenic (over 99 percent As_2O_3) fell slightly—from 317,548 kilograms during the first 6 months of 1950 to 301,808 kilograms in the first 6 months of 1951.

Asbestos

By Oliver Bowles and F. M. Barsigian

GENERAL SUMMARY

PRODUCTION of asbestos in Canada, our principal source, surpassed all previous records by a wide margin in 1951. Nevertheless, the demand for asbestos has increased so sharply that most grades were in short supply. Demand for the shorter grades, particularly group 7, was lighter during the latter part of the year. Shortages were more acute for Rhodesian chrysotile than for Canadian.

Although domestic sales exceeded the high record of 1949 by 19 percent, they represented only 6 percent of domestic requirements. Major production is in Vermont. Arizona furnished moderate supplies of chrysotile, including some of high-quality spinning grade. Several States reported small sales of amphibole asbestos.

As in 1950, imports and apparent consumption exceeded all previous records. Imports from Canada again attained an all-time high, but imports of low-iron chrysotile from Southern Rhodesia continued to decline—a condition that has created a critical situation with respect to this type of asbestos, which is obtainable from other sources only in quite limited quantities.

Acquisition of strategic grades for the National Stockpile continued to be difficult because industrial demand, of which a large percentage was directly or indirectly for the defense program, was quite urgent. Prices of Canadian asbestos were 10 to 25 percent higher in 1951 than in 1950. Vermont prices remained at 1950 levels until October 1951, when they were advanced to figures comparable with the corresponding Canadian grades. Prices were advanced further early in 1952.

PRODUCTION

As indicated in table 1, domestic production was 25 percent higher and sales 22 percent higher in 1951 than in 1950. Chrysotile was produced in Vermont and Arizona and amphibole in Georgia, North Carolina, and Oregon. So few companies have produced amphibole asbestos during recent years that separate figures cannot be published.

Alaska.—No asbestos was produced in 1951 from the Alaska deposit in the Kobuk River district, but Philip S. Hoyt, P. O. Box 83, Aguila, Ariz., reported some prospecting.

Arizona.—In 1951 chrysotile production in Arizona was somewhat higher than in the previous year. Some high-quality material suitable for the National Stockpile was recovered. The following firms and individuals were active: American Asbestos Cement Corp., P. O. Box 2033, Globe (on February 5, 1951, took over Wilson Cherry Creek mine, formerly operated by Gila Asbestos Co.); Apache Asbestos Mines, Inc., P. O. Box 983, Globe; Bear Canyon Mining Co., Globe; Dennis Brown, P. O. Box 328, Globe; Ned H. Brown, P. O. Box 1797, Clifton; Arthur Enders, P. O. Box 362, Globe; Charles Ireland, P. O. Box 374, Globe (lease ended May 1951—operation taken over by Frank Witte); D. W. Jaquays, 1219 South 19th Ave., Phoenix; Kyle Asbestos Mines of Arizona, P. O. Box 302, Globe; Metate Asbestos Corp., Globe; Phillips Asbestos Mines, Drawer 71, Globe; and Pine Top Asbestos Mines, Globe.

California.—Commercial production in California was at a standstill in 1951. A small amount of tremolite was reported sold to the Powhatan Mining Co. for use as a filter medium. The owners of the property, formerly operated by the Loma Blanca Mines, Inc., reported that their mine is open to lease. Prospecting and exploration were continued in California, some of it under Defense Minerals Exploration Administration loans, but no significant discoveries have yet been made.

Georgia.—Powhatan Mining Co., Woodlawn, Baltimore 7, Md., produced amphibole from mines in Meriwether and Rabun Counties. Industrial Minerals Corp., 30 North La Salle St., Chicago 2, Ill., reported development work on tremolite in Rabun County.

Montana.—Some exploratory work was conducted near Cliff Lake, Madison County, by Madisonian Mining & Milling Co. under a DMEA loan.

North Carolina.—Powhatan Mining Co. produced amphibole in Transylvania County near Lake Toxaway. Industrial Minerals Corp., 30 North La Salle St., Chicago 2, Ill., continued development work on amphibole deposits in Macon and Yancey Counties.

Oregon.—Philip S. Hoyt, P. O. Box 83, Aguila, Ariz., reported production in Oregon of a small amount of asbestos suitable for use as filter fiber.

Vermont.—The Vermont Asbestos Mines Division of the Ruberoid Co., 500 Fifth Ave., New York 18, N. Y., the largest producer of chrysotile in the United States, continued operation on an enlarged scale and also conducted exploratory work, partly under a DMEA loan.

Wisconsin.—The DMEA has approved a small exploration loan to determine the extent of a chrysotile deposit in eastern Marinette County. Results of the work are not yet available.

Digitized by Google

Wyoming.—The Philip Carey Manufacturing Co. was planning limited exploration of an asbestos deposit on Casper Mountain, Natrona County, under a DMEA loan.

CONSUMPTION AND USES

As indicated in table 2, apparent consumption of raw asbestos in the United States was about 10 percent higher in 1951 than that in 1950, which itself was an all-time high record. Asbestos is used in a multitude of industrial applications; therefore, its consumption in general moves in consonance with the trend of industrial production. Asbestos is also used extensively as a constituent of building materials and insulation products; therefore its consumption is particularly influenced by the volume of building construction. These trends are shown graphically in figure 1.

TABLE 2.—Apparent consumption of raw asbestos in the United States, 1942–51

Year	Short tons	Value	Year	Short tons	Value
1942	433, 949	$21, 582, 096	1947 [1]	616, 194	$30, 303, 777
1943	445, 902	23, 351, 483	1948 [1]	675, 746	37, 975, 742
1944	389, 241	18, 864, 291	1949 [1]	532, 708	32, 401, 654
1945	378, 030	15, 926, 622	1950 [1]	727, 002	46, 124, 871
1946	458, 727	17, 880, 214	1951 [1]	796, 992	58, 771, 276

[1] 1947–50 figures revised owing to change in basis of calculation. Export figures for 1947–51 used in arriving at apparent consumption include material that has been imported and subsequently exported without change (exports of "foreign" merchandise).

PRICES

Prices of Canadian asbestos, as quoted in short tons, f. o. b. mines, in the magazine Asbestos were raised substantially on January 15, 1951, to the following levels: Group 1 (Crude No. 1) $1,100–$1,500; group 2 (Crude No. 2, Crude Run-of-Mine, and Sundry), $485–$900; group 3 (Spinning Fiber), $275–$450; group 4 (Shingle Fiber), $135–$151; group 5 (Paper Fiber), $95–$119; group 6 (Waste, Stucco, or Plaster), $70; group 7 (Refuse or Shorts), $32–$63. These prices remained in effect throughout the year.

Vermont prices, quoted in short tons f. o. b. Hyde Park or Morrisville, Vt., remained at the December 1950 level until October 1951. In June 1951, however, a new item was introduced for Vermont fibers, namely, Spinning and Filtering Fibers, which were quoted at $254.10–$274.45. In October Vermont prices were increased to the following levels: Group 3 (Spinning and Filtering), $279.50–$302; group 4 (Shingle Fiber), $135–$162; group 5 (Paper Fiber), $81.50–$115; group 6 (Waste, Stucco, or Plaster), $71.40; group 7 (Refuse or Shorts), $34–$63. These prices remained in effect for the balance of the year. Prices of all grades, both Canadian and Vermont, except Canadian Crude No. 1, were again advanced substantially in January 1952.

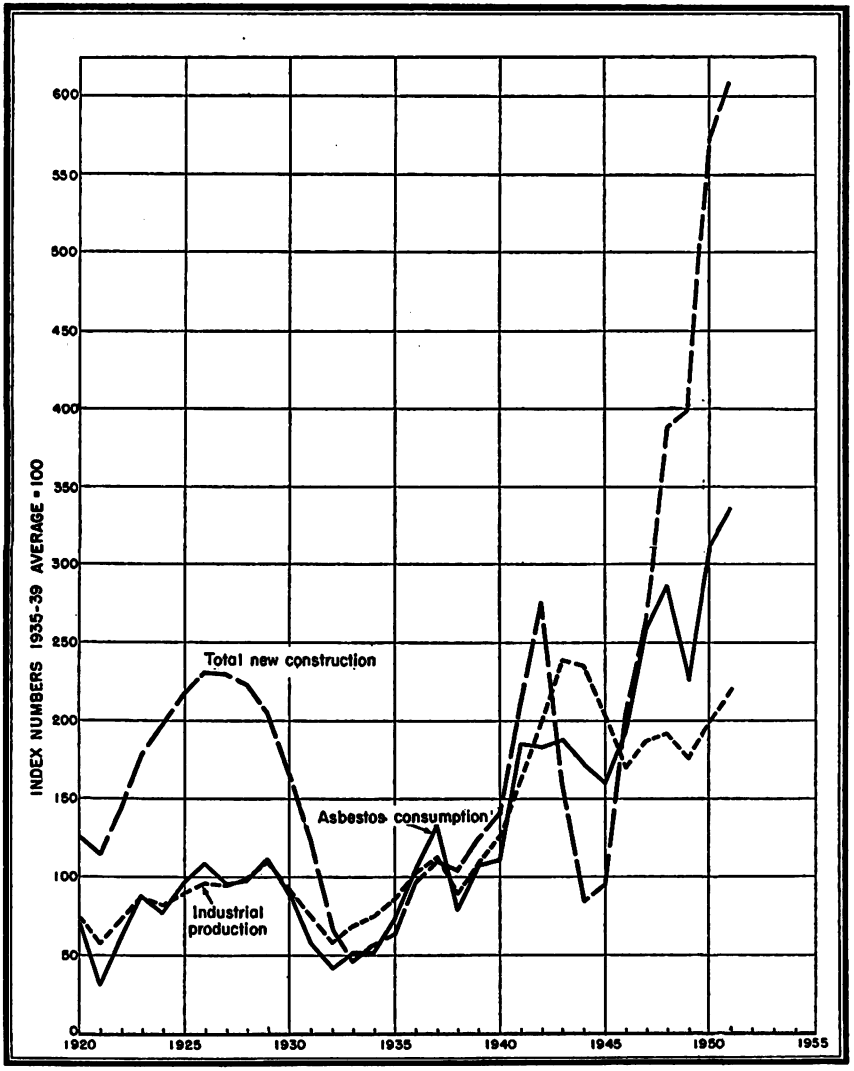

FIGURE 1.—Consumption of asbestos compared with total new construction and industrial production, 1920–51. Statistics on value of construction from Bureau of Foreign and Domestic Commerce and on industrial production from Federal Reserve Board.

FOREIGN TRADE [1]

Imports.—The United States is the largest consumer of asbestos in the world but produces only a small percentage (6 percent in 1951) of its requirements. Accordingly, foreign supplies are essential to

[1] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Digitized by Google

the asbestos-products industries. In 1951 imports were 8 percent higher than in 1950. About 95 percent of the total imports originated in Canada, 3 percent in the Union of South Africa, and 1 percent in Southern Rhodesia. On a value basis the African percentages are much higher.

[1] Revised figure.
[2] Includes 10 tons ($2,715) of blue (crocidolite) crudes in 1950 and 512 tons ($52,065) of amosite crudes in 1951, credited by the U. S. Department of Commerce to Mozambique; 100 tons ($9,400) amosite crudes credited to French West Africa; 140 tons ($34,115) credited to Southern Rhodesia; and 6 tons ($2,002) blue (crocidolite) crudes credited to United Kingdom. Since Mozambique is not an asbestos producer and the Union of South Africa is the only producer of amosite, appropriate adjustments have been made by the Bureau of Mines.
[3] Revised to none.
[4] Includes 28 tons ($12,545) of blue (crocidolite) crudes credited by the U. S. Department of Commerce to Chile.
[5] Classified by U. S. Department of Commerce as amosite crude; reclassified by Bureau of Mines as mill fibers.

Exports.—Exports of unmanufactured asbestos were somewhat smaller in 1951 than in 1950. Because of current shortages of spinning fibers some measure of export control was deemed necessary, and export licenses were required beginning late in 1951. As indicated in table 4, the value of asbestos products exported increased sharply.

TECHNOLOGY

Further progress has been made in reducing the iron content of Canadian chrysotile to make it a suitable substitute for the low-iron chrysotile obtained in decreasing quantities from Southern Rhodesia. Certain grades of low-iron Quinterra paper, made of purified Canadian short-fiber asbestos by the Johns-Manville Corp., are now on the market for wrapping wire and other insulation purposes. Raybestos-Manhattan, Inc., is continuing research on low-iron Novabestos paper; a high-quality paper of this type is now made of combined

Digitized by Google

fiberglass and asbestos. Experiments by the Naval Research Laboratory on deironing asbestos with a Vortrap, to which reference was made in the Asbestos chapter for 1950, were continued, but no definite results were announced.

Progress is reported on fiberglass research, particularly on high-silica fibers that will give better service than soda-lime-glass fibers, as substitutes for asbestos. To make such fibers in submicron sizes is difficult, but progress has been achieved.

Claims have been made that the Aerofall mill has advantages over standard equipment, both in percentage of recovery and in grade of the fiber produced. This mill reduces the fiber-bearing rock by abrasion and impact in a single stage. Reduction is accompanied by air classification. Details of the mill and results of tests have been published.[2] It has been reported that an Aerofall mill is or will be installed in the Beaver mill of the Asbestos Corp. in Quebec and two such machines in the Rhodesian Monteleo mill, 15 miles south of Shabani, Southern Rhodesia.

The physical and chemical properties of the various types of asbestos have been described in some detail by Badollet.[3] The data presented comprise information assembled by search of the literature, supplemented by experimental work.

WORLD REVIEW

Official statistics of world production for 1951 are far from complete, but estimates for unreported countries are included in the total shown in table 6. New figures or improved estimates have necessitated substantial revisions in the totals listed for 1946–50. The total output of all producing countries gained substantially in 1950 and 1951.

CANADA

Canadian asbestos shipments in 1951 attained an all-time record of 973,198 short tons, valued at $81,584,345, compared with 875,344 short tons, valued at $65,854,568, in 1950—a gain of 11 percent in quantity and 24 percent in value. The following companies were operating in the Quebec area in 1951: Asbestos Corp., Ltd.; Johnson's Co.; Bell Asbestos Mines; Canadian Johns-Manville Corp.; Nicolet Asbestos Mines, Ltd.; Quebec Asbestos Corp.; and Flintkote Mines, Ltd. Further expansion in production is in prospect. The Jeffrey mill of Canadian Johns-Manville Corp. is being modernized. Asbestos Corp., Ltd., is planning extensive mill construction at the Vimy Ridge deposit, where large reserves of asbestos-bearing rock have been proved by diamond drilling. The new mill of Johnson's Co. at Black Lake was being constructed in 1951. United Asbestos Corp., Ltd., is taking steps to develop its promising deposit under Black Lake. Expanding uses for the shorter grades of Canadian asbestos are described by Rukeyser.[4]

Munro deposit has been published.[5] Little progress is reported by Teegana Mines, Ltd., in developing its property near South Porcupine in Deloro Township, Ontario.

There is increasing interest in the McDame Creek asbestos deposit in northern British Columbia, now being developed by Conwest-Exploration Co., Ltd. The fiber is said to be high-quality spinning-grade chrysotile. Production is expected in 1953.

SOUTHERN AFRICA

Southern Rhodesia.—As indicated in table 8, asbestos production in Southern Rhodesia in 1951 was considerably higher than in 1950. Principal production is from the Shabani mines and from operations in the Mashaba and Filabusi districts, controlled by Turner & Newall, Ltd., of Manchester, England. In 1951 a new company was planning mining and milling operations on a deposit 15 miles from Shabani. It is named Rhodesia Monteleo Asbestos, Ltd., a subsidiary of African & European Investment Co., Ltd., of Johannesburg. Several other mines and prospects have been recorded, but their output has been quite small.

TABLE 8.—Asbestos produced in Southern Rhodesia, 1946–51

Year	Short tons	Value	Year	Short tons	Value
1946	55,872	£1,676,503	1949	79,638	£3,986,703
1947	54,094	1,738,484	1950	71,527	4,615,490
1948	68,897	2,604,623	1951	77,663	5,452,108

Union of South Africa.—Output of asbestos in the Union continued the remarkable gains that have characterized recent years. Production in 1951 was 23 percent greater than in 1950. Amosite production (*see* table 10) continued its upward trend, 1951 output exceeding that of 1950 by 28 percent. Current production, however, includes a larger proportion of the shorter grades than formerly. Production of Transvaal crocidolite (blue asbestos) was about the same as in 1950, but the output of Cape blue advanced 19 percent. Production of chrysotile increased 36 percent. Kinlock Asbestos (Pty.), Ltd., is a substantial producer. The Doyershock Asbestos Mine (Pty.), Ltd., adjoining the Kinlock property, produces a moderate tonnage. The Munnick-Myburgh mine, which has been inactive for some years, has been reopened by African & European Investment Co., Ltd. A new mill having a capacity of 8,000 tons of rock a month has been completed.

The current heavy demand for short fibers has created interest in recovery of shorts in South Africa. The long distance of the African mines from markets makes it imperative that every possible economy be practiced if any profit is to be made from shorts.

Sinclair has described crocidolite mining.[6]

Total	30,142	45,735	70,917	[2] 87,414	107,368

[1] Data from Union of South Africa, Department of Mines, quarterly reports.
[2] Revised figure.

Swaziland.—The Havelock mine close to the Transvaal border has become an important producer. Output in 1951 reached an all-time high. It is reported that a new mine adjacent to the Havelock is being worked by Msuali Asbestos Co., also known as African Chrysotile Co.

OTHER COUNTRIES

Bolivia.—The Province of Chapare has the distinction of possessing the only known commercial deposit of crocidolite (blue asbestos) in the Western Hemisphere. The material is in demand for air filters, and the small imports are purchased mainly for the National Stockpile.

Brazil.—Deposits of chrysotile asbestos are worked in a small way at Djalma Dutra, State of Bahia, and near Nova Lima, State of Minas Gerais.

Colombia.—Active measures are being taken to develop chrysotile asbestos deposits at or near Yarumal, State of Antioquia. An official of Emergency Procurement Service has examined a deposit at Neira, near Manizales, State of Caldes. Samples submitted to the Bureau of Mines were found to consist in part of chrysotile and in part of nemalite, which is fibrous brucite ($Mg(OH)_2$). Possible utilization of the latter fibers is now under investigation. All of the chrysotile is of the slip-fiber type.

Morocco.—A deposit of high-quality chrysotile has been worked to some extent at N'Cob, about 185 miles by road from Marrakech.

Asphalt and Related Bitumens

By A. H. Redfield[1] and Willa D. Granacher

GENERAL SUMMARY

DOMESTIC demand[2] for petroleum asphalt (including small quantities of imported lake asphalt and, in 1950, of grahamite) was nearly 13 percent larger in 1951 than in 1950, but export demand was 28 percent greater. As export demand in 1951 was less than 1½ percent of the total demand, the total demand increased only 13 percent from 1950 to 1951. In numerical terms, an increase of 1,372,686 short tons in domestic demand, augmented by an increase of 39,620 tons in export demand, was met by an increase of 1,466,356 tons in refinery production and an increase of 119,442 tons in imports of petroleum and lake asphalt. Included in the change in domestic demand was the effect of an increase in refinery stocks of asphalt of 241,275 tons during 1951 compared with an increase of 68,179 tons in 1950.

TABLE 1.—Supply and distribution of asphalt and related bitumens in the United States, 1950–51, in short tons

	1950	1951
SUPPLY		
Native asphalt and related bitumens:		
Production	1,250,862	1,443,955
Imports (chiefly lake asphalt)	5,863	6,304
Petroleum asphalt (excluding road oil):		
Production	10,589,099	12,055,455
Imports	323,571	442,572
Stocks, Jan. 1	894,182	962,361
Total supply	13,063,577	14,910,647
DISTRIBUTION		
Native asphalt and related bitumens:		
Domestic demand[1]	[2] 1,232,441	1,419,037
Exports	[2] 18,421	24,918
Petroleum asphalt (excluding road oil):		
Indicated (apparent) domestic demand[1]	[2] 10,706,729	12,079,811
Exports	[2] 143,625	183,245
Stocks, Dec. 31	962,361	1,203,636
Total distribution	13,063,577	14,910,647

[1] Domestic demand for native asphalt excludes, and that for petroleum asphalt includes, lake asphalt, since this has the same sorts of uses as the manufactured product.
[2] Revised figure.

NATIVE ASPHALT AND BITUMENS

Bituminous Rock.—Sales of bituminous rock by producers in the United States increased from 1,184,676 short tons in 1950 to 1,378,434

[1] Deceased.
[2] The term "domestic demand" as used in this chapter means apparent consumption, that is, production plus net imports and changes in refiners' stocks.

Digitized by Google

tons in 1951 and in value from $3,522,308 to $4,159,259. Bituminous limestone amounted to 1,071,955 tons valued at $2,737,056 in 1950 and 1,247,940 tons valued at $3,178,323 in 1951. Bituminous sandstone totaled 112,721 tons valued at $785,252 in 1950 and 130,494 tons valued at $980,936 in 1951. The average sales value of bituminous limestone—$2.55—remained the same as in 1950. The average sales value of bituminous sandstone increased from $6.97 per ton in 1950 to $7.52 in 1951.

Gilsonite.—Sales of gilsonite by producers in northeastern Utah decreased from 66,186 tons valued at $1,774,330 in 1950 to 65,521 tons valued at $1,895,374 in 1951. The average sales value per ton at the mine or railhead increased from $26.81 in 1950 to $28.93 in 1951.

MANUFACTURED OR PETROLEUM ASPHALT

Production.—Petroleum refineries in the United States produced 12,055,500 short tons of asphalt in 1951, a 14-percent increase over the 10,589,100 tons produced in 1950. The increases were general but were greater in the East Coast, Indiana-Illinois-Kentucky, etc., and Oklahoma-Kansas-Missouri districts.

Stocks.—Stocks of asphalt held at refineries increased 25 percent from 962,400 short tons on December 31, 1950, to 1,203,600 tons on December 31, 1951. The increases were general throughout the United States except in the Louisiana-Arkansas district, where stocks were reduced.

TABLE 2.—Supply and disposition of petroleum asphalt (exclusive of road oil) at petroleum refineries in the United States in 1951, by refinery district, in short tons

District	Production	Receipts[1]	Stocks		Consumption by producers, transfers,[2] losses, and exports	Sales to domestic consumers
			Jan. 1	Dec. 31

Sales.—Sales of petroleum asphalt to domestic consumers increased 11 percent in quantity from 1950 to 1951 and, because of higher prices, 22 percent in value. The average sales price per short ton increased from $16.87 in 1950 to $18.47 in 1951. The greatest increases in both tonnage and in value were in the Texas, East Coast, and Indiana-Illinois-Kentucky, etc., districts. In contrast to the general trend, the Louisiana-Arkansas district showed a decrease of 7 percent in its quantity of sales but a 5-percent increase in value in 1951 over 1950.

Of the total petroleum asphalt sold to domestic consumers in 1951, 27 percent was manufactured from foreign petroleum, imported mainly from Venezuela, Colombia, Mexico, and the Persian Gulf, compared with 25 percent in 1950. Although runs of foreign crude to stills increased only 3 percent from 1950 to 1951, sales of asphalt made from foreign crude increased 19 percent from 1950 to 1951. Of the foreign crude processed, 8 percent was converted to asphalt in 1950 and a little over 9 percent in 1951. Ninety-seven percent of the asphalt made from foreign petroleum in 1951 was manufactured in east coast refineries, compared with 94 percent in 1950.

California	1,602,022	25,257,572	1,744,279	30,696,277
Total United States	10,528,466	177,563,593	11,700,802	216,104,996

Highway and street construction and airport-runway surfacing used (in the form of paving asphalt, paving flux, cutback asphalts, and asphalt emulsions) 71 percent of the total asphalt sold to domestic consumers by petroleum refineries in 1951 compared with 66 percent in 1950. Sales of all grades of asphalt devoted wholly or principally to street and road construction increased 20 percent in 1951 over 1950.

Roofing manufacture made the second largest demand for asphalt, absorbing 27 percent of the total in 1950 and 25 percent in 1951. Although sales of prepared roofing and asphalt siding reported to the Bureau of the Census decreased 9 percent—from 65,024,467 (revised figure) squares in 1950 to 59,116,749 in 1951—and of saturated felt increased 2 percent—from 650,389 (revised figure) short tons in 1950 to 662,961 in 1951—domestic sales of roofing asphalt and roofing flux combined increased 4 percent—from 2,846,623 short tons in 1950 to 2,962,444 tons in 1951. These figures do not include roofing asphalt and flux consumed by the refining companies in factories owned by themselves or by affiliated companies making prepared roofing and siding and saturated felts.

Sales of asphalt emulsified with water were 85 percent greater in 1951 than in 1950. Petroleum refineries sold 119,489 tons (28,151,609 gallons) valued at $2,440,692 in 1950 and 216,247 tons (51,034,292 gallons) valued at $4,672,705 in 1951. In addition, 75,558,691 gallons valued at $9,323,628 in 1950 and 142,084,036 gallons valued at $16,148,374 in 1951 were sold by secondary producers that purchased asphalt from petroleum refineries and manufactured it into emulsions. Accordingly, total known sales of emulsified asphalts and fluxes increased 84 percent in quantity—from 104,710,300 gallons (444,441 tons) in 1950 to 193,118,328 gallons (818,298 tons) in 1951—and 76 percent in value—from $11,764,320 in 1950 to $20,821,079 in 1951.

APPARENT CONSUMPTION

The apparent domestic consumption of petroleum asphalt increased 13 percent in 1951 over 1950. The apparent average monthly domestic consumption of petroleum asphalt (including small quantities of imported lake asphalt and grahamite, which have similar uses and are supplementary to petroleum asphalt) increased from 892,227 (revised figure) short tons in 1950 to 1,006,651 in 1951. Total apparent consumption was 10,706,729 tons (revised figure) in 1950 and 12,079,811 in 1951.

DISTRIBUTION BY RAIL

Revenue-freight statistics showing the tonnage of each important commodity originated and terminated in each State by class I railroads, formerly compiled and issued by the Interstate Commerce Commission, were discontinued by the Commission at the end of 1950. Accordingly an index, however imperfect, of the consumption of asphalt by States is no longer available. Apparently, however, increasing quantities of asphalt are delivered to consumers by waterways, minor railroads, and motor trucks, as quantities terminated by class I railroads were equivalent to only 62 percent of the apparent consumption of asphalt in the United States in 1949 and only 53 percent of the total in 1950.

FOREIGN TRADE[3]

Imports.—Imports of natural asphalt and bitumen into the United States totaled 5,863 short tons valued at $136,003 in 1950 and 6,304 tons valued at $112,007 in 1951. Imports of lake asphalt from Trinidad increased from 4,855 tons valued at $66,953 to 6,270 tons valued at $110,940. Imports of grahamite from Cuba amounted to 880 short tons valued at $27,880 in 1950, but none was imported in 1951. Imports of solid petroleum asphalt increased from 308,959 short tons valued at $3,275,967 in 1950 to 422,345 tons valued at $5,013,730 in 1951. Netherlands Antilles was the principal source. In addition, the United States received 80,365 barrels (14,612 tons) of liquid petroleum asphalt valued at $205,031 in 1950 and 111,250 barrels (20,227 tons) valued at $280,294 in 1951. Nearly all of these imports for 1950 came from the Netherlands Antilles and those for 1951, from Venezuela.

Exports.—The tonnage of natural asphalt, unmanufactured, exported from the United States increased from 18,421 short tons (revised figure) valued at $910,910 (revised figure) in 1950 to 24,918 tons valued at $1,277,783 in 1951. Of the 1951 exports, 77 percent went to Europe, notably to the United Kingdom, France, Germany, Italy, Sweden, Netherlands, Belgium and Luxembourg, Denmark, and Switzerland. Canada received 9 percent of the total, Brazil 2 percent, India 2 percent, and Mexico 2 percent. Exports of petroleum asphalt from the United States increased from 143,625 tons (revised figure) valued at $4,519,641 (revised figure) in 1950 to 183,245 tons

[3] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Grand total	[3] 143,625	[3] 4,519,641	183,245	6,391,462

[1] In addition, exports of "petroleum asphalt manufactures" were valued as follows: 1950—$381,019; 1951—$2,351,776 (quantity not available).
[2] Revised figure.
[3] Total for Europe revised to include Turkey; formerly included with Asia.

ROAD OIL

Road oil is less easy to define in terms of its physical properties than in terms of its practical uses. Any residue of petroleum distillation, or blend of residues and distillates, that is liquid enough to be applied easily to a roadway without preheating, that is sufficiently cohesive to bind the surface particles into a surface that is moderately dust-free in dry weather and not too muddy in wet weather, that is cheap enough to be bought as surface dressing for secondary roads built for light vehicular traffic may be sold as road oil. Consequently, statistics submitted to the Bureau of Mines by the refiners may confuse road oil with asphalt fluxes and cutback asphalts. Residual oils that had been stored as fuel oils may find their final use as road dressing. Consequently, adjustments have to be made each year for transfers into and out of road-oil stocks to achieve a balance between recorded figures of road-oil production and stocks at the beginning of the year on the one hand and domestic sales and stocks at the end of the year on the other. The same type of oil may be designated by one refiner as "road oil" and by another as "slow-curing cut-back asphalt." A railroad tank-car of "fuel oil" may be diverted in transit to a highway contractor and spread upon a highway.

Sales of road oil by petroleum refineries in the United States decreased 11 percent in quantity—from 7,326,000 barrels in 1950 to 6,494,000 barrels in 1951—but because of higher prices decreased only 1 percent in value—from $16,876,000 in 1950 to $16,651,000 in 1951. Of the total sales of road oil to domestic consumers, 71,291 barrels valued at $233,269 in 1950 and 59,832 barrels valued at $208,349 in 1951 were made in east coast refineries from foreign petroleum, imported chiefly from Venezuela, Colombia, and Mexico.

Barite

By Joseph C. Arundale and F. M. Barsigian

GENERAL SUMMARY

IN 1951 the domestic barite industry produced 845,600 short tons of primary barite;[1] 52,800 short tons was imported; a record 950,900 short tons was consumed. Over 62 percent of the tonnage consumed was used in oil-well drilling muds. New production was reported from Montana, and a new producer began operations at Upper Brookfield, Nova Scotia.

[1] Includes some witherite.

Barite is growing rapidly in importance to the national economy. It has been mined in the United States since the middle of the 19th century, when production first was reported in Virginia. A few years later it was discovered in Missouri, where it has been produced continuously for 100 years. Several significant events have marked development of the domestic industry. The first use of barite was as a paint filler. In 1892 a lithopone industry was established in the United States, and this created the second major market for barite. Production of barite in Georgia began in 1901 and in Kentucky in 1903. The first domestic barium-chemical plant began operation at Blue Island, Ill., in 1908. Washers and jigs were installed in Georgia

[1] The term "primary barite," as used in this chapter, applies to barite as first offered to the trade, whether lump, crushed, or ground. Where ground barite has been reported to the Bureau of Mines as original production, an estimate of the value of the lump equivalent of the ground has been assigned to such tonnage

Digitized by Google

and Tennessee in 1914–16 and in Missouri in 1923. In 1926 the use of barite as a weighting agent in drilling mud was patented; over two-thirds of the domestic output was employed for this purpose in 1951. The use of barite as a flux in glass began in 1928. The deposit, from which barite was being produced in Arkansas in 1951, was discovered in 1900, but sustained production did not begin until 1941, when this barite first was recovered by flotation on a commercial scale.

DOMESTIC PRODUCTION

Mine production of barite, which had slumped after the record year 1947, surged to a near-record 845,600 short tons in 1951 under the impetus of an accelerated well-drilling program. Demand, which had begun to increase in the latter part of 1950, continued to expand during 1951. By the end of the year shortages were being reported, and producers were attempting to increase their capacities. Arkansas again was eminent in output, with a record tonnage going to the well-drilling trade. Missouri was second in rank, with a substantial increase over the previous year, but did not reach 1947 output.

Arizona.—The Arizona Barite Co. continued to produce ground barite for the well-drilling trade at its mine and mill near Mesa.

Arkansas.—The two producers in Arkansas—Magnet Cove Barium Corp. and Baroid Sales Division of National Lead Co.—increased their output to supply a record tonnage of ground barite to the well-drilling industry.

TABLE 2.—Domestic barite sold or used by producers in the United States, 1949–51, by States

State	1949		1950		1951

Digitized by Google

California.—Only one producer was operating in California during 1951—Barium Products, Ltd., at the Almanor mine near Greenville in Plumas County. Crude barite from this mine was ground at Modesto.

Georgia.—Several producers operated in Georgia during the year, and output went principally to well-drilling on the Gulf coast and to eastern glass and chemical producers.

Idaho.—Simplot Fertilizer Co. produced barite near Hailey and ground it at Pocatello. This product was sold for well-drilling.

Missouri.—1951 marked 100 years of continuous barite production. During the year new producers and processors increased the State's total output.

Montana.—A new producer, F. & S. Contracting Co., reported production of barite near Greenough, Missoula County.

Nevada.—Baroid Sales Division of National Lead Co. temporarily discontinued production in Nevada, but shipments were made from stocks. Barium Products, Ltd., continued to produce at two locations near Battle Mountain and shipped the product to Modesto, Calif. California-Nevada Barytes Mines, Division of Glidden Co., produced from the Jumbo mine in Tonopah County and the Barium King mine in Lander County.

New Mexico.—The Mex-Tex Mining Co. produced barite from the Royal Flush mine near Bingham and processed it at its mill south of San Antonio, N. Mex. Mudrite Chemicals discontinued production near Hatch.

South Carolina.—Industrial Minerals, Inc., produced barite near Kings Creek for eastern markets.

Tennessee.—L. A. Wood and B. C. Wood continued production near Sweetwater.

CONSUMPTION AND USES

Domestic consumption of barite about doubled in the 10 years ended in 1951. The most significant changes in consumption of barite in 1951 were the large increases in tonnage used in well-drilling muds and as aggregate in concrete. Completion of 44,516 wells (including service wells) with a total footage of 172,331,000 feet set a new record for well drilling in the United States in 1951. The average depth of holes continued to increase. This activity created an unprecedented demand for barite as the weighting material in drilling fluids required in areas with high formation pressures.

The use of barite as a dense aggregate in concrete was growing rapidly. By 1951 heavy concrete was used principally for weighting oil and gas pipelines in swampy areas and in river crossing. Barite-containing plasters had been used for years in some X-ray rooms, but a newer use for barite was as a dense aggregate in concrete radiation barriers at atomic energy installations.

PRICES

Crude.—Late in 1951 trade journal quotations on Missouri crude increased from $9.50 to $10.40 for barite with a minimum 94 percent $BaSO_4$ and less than 1 percent iron; 93 percent $BaSO_4$ was increased from $9.25 to $10.15 per short ton, f. o. b. mines. Georgia crude, jig, and lump was unchanged at $13–$13.50 per long ton.

Ground.—Missouri, water-ground, floated, bleached was unchanged at $37.60 per short ton on carlots, f. o. b. works. Georgia, beneficiated in paper bags was unchanged at $16–$18 per net ton.

Witherite.—Prices on airfloated witherite (barium carbonate) were unchanged at $65 per short ton on carlots and $72 on less than carlots.

TABLE 9.—Range of quotations on barium chemicals in 1951

[Oil, Paint and Drug Reporter]

Barium carbonate, precipitated, bags, 10 tons and up, works	short ton	$72.50 –$87.50
Barium chlorate, kegs, works	pound	.30 – .35
Barium chloride, technical, bags, carlots, works	100 pounds	7.80
Barium chromate, bags, freight equaled	pound	.31½– .32
Barium dioxide (peroxide), drums, carlots, works	do	.12 – .15
Barium hydrate, crystals, bags	do	.09 – .09½
Barium nitrate, barrels, carlots, works	do	.11½– .15¼
Barium oxide, ground, drums, carlots, works	do	.11 – .12
Blanc fixe (dry):		
Direct process, bags, carlots, works	short ton	90.00
Byproduct, bags, carlots, works	do	85.00 –100.00
Lithopone: [1]		
Ordinary, bags, carlots, delivered	pound	.07½
Less carlots, same basis	do	.08¼– .08½
Titanated (high-strength), bags, carlots, delivered	do	.09⅝
Smaller lots	do	.10⅝

[1] Pacific coast prices on lithopone 1 cent per pound higher.

FOREIGN TRADE [2]

Barite.—The United States annually imports a considerable tonnage of barite to supplement domestic supplies. In the past most of such imports went to eastern chemical producers. However, some recent shipments were made to the Gulf coast area for use in well-drilling.

Imports of barite from Nova Scotia continued to increase, but imports from other sources were small. Yugoslavia, which supplied a considerable tonnage in 1949 and 1950 to chemical producers on the east coast, suspended shipments in 1951 but was expected to resume in 1952.

The Tariff Act of 1930 established the import duty on crude barite at $4 per long ton and at $7.50 per long ton of ground barite. As a result of the General Agreement on Tariffs and Trade signed at Geneva on October 30, 1947, the duty on crude barite was reduced to $3.50 per long ton with a rate of $3.20 accorded to Cuba. The duty on ground barite was unchanged. A similar agreement made at Torquay, England, effective June 6, 1951, reduced the rate on crude to $3 per long ton from all sources, and the rate on ground barite was lowered to $6.50 per long ton.

Witherite.—The only witherite produced in the United States was that which occurred as an "impurity" in barite. All imports of witherite came from Great Britain.

WORLD REVIEW

Barite deposits are numerous and widespread throughout the world, and many countries produce barite for domestic consumption or export. In general, the important consuming countries have production adequate to their needs or have nearby supplies. However, some do import barite for economic reasons or because of temporary inadequacy of domestic production facilities.

TABLE 14.—World production of barite, 1946–51, by countries, in metric tons[1]

Austria.—Barite was produced in Austria from the Grosskogel, Fieberbrunn-Niederkogelalpe, and the Kitzbugler Horn mines in Tirol province in the French zone and the Sonnwendstein Mine in Lower Austria in the Russian zone.[3]

Canada (Nova Scotia).—The new barite-processing mill of Maritime Barytes, Ltd., at Upper Brookfield, Colchester County, was officially opened on July 14, culminating 3 years of effort.

The company was reported to have 110 acres of surface rights and several square miles of mining rights in the Brookfield area. Diamond drilling revealed that the ore extended at least 350 feet down and 500 feet back from the surface of the outcrop. Enough ore was estimated to be available for recovery by open-pit methods to run the processing mill on a 24-hour basis for 10 years.

The processing plant has a grinding capacity of 120 tons per 24 hours. However, the company indicated that production was to be aimed at 50 to 60 tons of the white filler barite during the 24-hour period, with 1 ton of well-drilling-grade barite produced as a virtual byproduct of each 2 tons of white barite. The company reportedly was planning to emphasize the production of white barite. A production figure of 10,000 tons per year of the white barite was mentioned to the American consulate at Halifax. The white barite was expected to test 99 percent $BaSO_4$, with the barite for use in oil-well drilling testing 97 to 98 percent $BaSO_4$.

The president of the Maritime-Barytes, Ltd., indicated that, even if only 5,000 tons of white filler barite could be marketed each year, the plant would be well beyond the break-even point. With an estimated output of 10,000 tons of the white variety, however, and consequent production of the oil-drilling-grade barite, a total volume of 15,000 tons of the 2 varieties would be available for market.

Figures for barite production and shipments from the Canadian Industrial Minerals mine at Walton in the first quarter of 1951 follow: 6,112 short tons mined, 3,062 tons milled, and 112 tons of ground barite sold. No sales of crude barite were made in the period. Production and sales were down sharply from the previous quarter (last quarter of 1950). No shipments can be made from the port of Walton Village during January, February, and March because of navigational difficulties; therefore, the sharp decline in sales and shipments is an annual occurrence. However, output and sales increased in April and May. In May, 14,176 tons was mined (none in April); milled barite totaled 7,932 for April and May. Sales of crude barite were 12,939 tons in May (none in April), and sales of ground barite totaled 8,781 tons for both April and May.

The last quoted price for "Cimbar" ground barite was $C13.80 per ton, f. o. b. mine. This price, covering costs for milling and bagging of about $C4.70 per ton as well as mining costs, was considered by the company to be the lowest at which the product could be offered.[4]

Philippine Republic.—A small barite mine was opened in 1950 at Lobo, Batangas Province. The mine produced 200 tons of ore for local consumption. The company was endeavoring to import equipment for a grinding mill, with the ultimate objective of exporting ground barite to oil firms in the East Indies.[5]

Spain.—Production (in 1949) of barite in Spain came from 11 operations in 8 provinces: two each in Almeria, Gerona, and Leon, and one each in Castellon, Guadalajara, Navarro, Santander, and Tarragona.[6]

Bauxite

By Horace F. Kurtz

GENERAL SUMMARY

ALTHOUGH many mineral deposits containing the element aluminum occur in large quantities throughout the earth's crust, bauxite, a rock consisting chiefly of aluminum hydrate minerals, has been the principal ore from which the metal is recovered and high-aluminum artificial abrasives, refractories, and chemicals are produced. Bauxite has been an important raw material to these nonmetal industries, but the growth of the bauxite industry has nearly paralleled that of the major bauxite consumer, the aluminum industry. A consistently increasing demand for bauxite became abnormally great during World War II, when aluminum production was expanded for military uses. Postwar metal surpluses and the lowered demand for aluminum temporarily reduced bauxite requirements; however, a steadily increasing per capita consumption of aluminum, together with plans for expanding the aluminum industry to meet new defense requirements, indicate that by 1953 bauxite consumption will surpass the peak level attained during the war.

TABLE 1.—Salient statistics of bauxite in the United States, 1935–51, in long tons

	1935–39 (average)	1940–44 (average)	1945–49 (average)	1950	1951
Crude-ore production (dry equivalent)	347,411	2,606,980	1,178,612	1,334,527	1,848,676
Imports (as shipped)	401,209	947,726	1,718,049	[1] 2,516,247	2,829,929
Exports (as shipped)	79,903	208,217	81,450	[1] 45,406	89,948
World production	3,260,000	7,840,000	6,040,000	[1] 8,030,000	10,480,000

[1] Revised figure.

Since the Guiana bauxite deposits were opened in the 1920's, a gradual trend toward greater dependence on imports developed in the United States. About 53 percent of the bauxite actually used in the 6 years since World War II was of foreign origin, chiefly from Surinam, and this percentage was expected to increase after shipments from Jamaica were begun in 1952. In addition to actual consumption, large quantities were imported for the National Strategic Stockpile in recent years. The security risks of relying more on imported ore were expected to be partly offset by the proximity of the new source of supply, since the shipping lane from Jamaica is considerably shorter and more easily protected than that from other foreign suppliers.

Total world reserves of bauxite exceeded most estimates of world requirements for the remainder of the twentieth century, although most of the leading consuming countries were deficient in reserves. Bauxite shortages in the United States stimulated the search for new techniques, but the fact that bauxite was the only ore from which aluminum was recovered on a commercial scale in 1951 indicated that

Digitized by Google

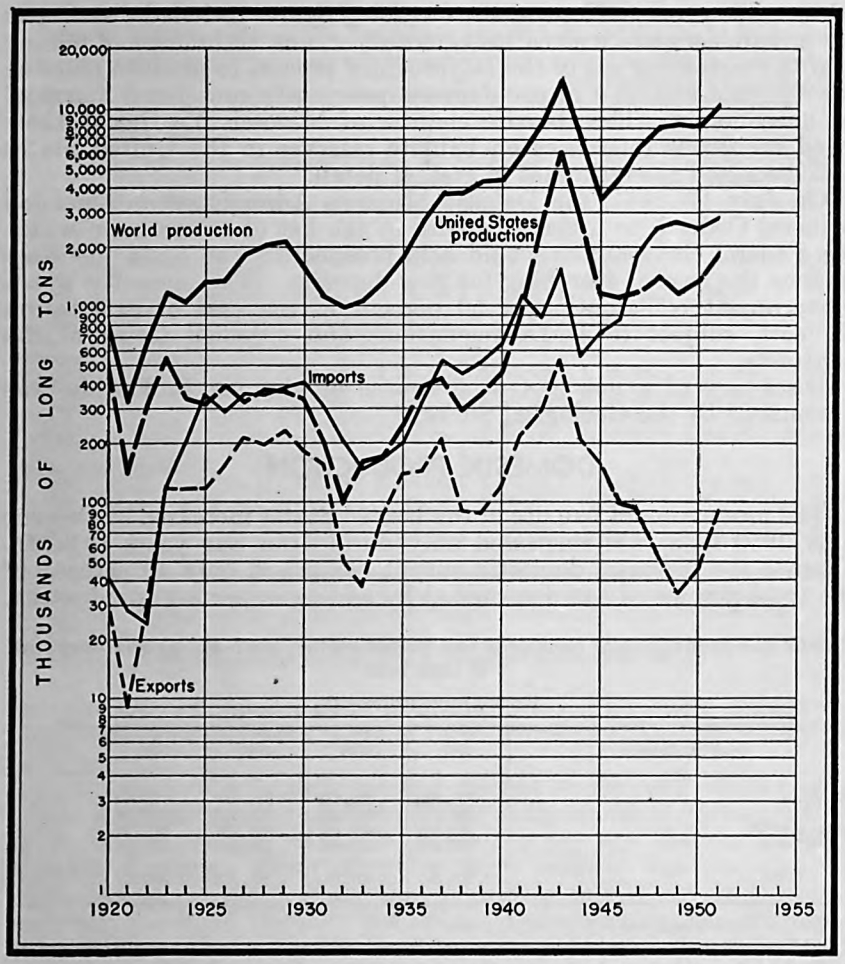

FIGURE 1.—Domestic production, imports, exports, and world production of bauxite, 1920–51.

no method of recovering the metal from other materials had yet been proved competitive. It was recognized that raw materials other than bauxite may become economical substitutes through development of processes involving cheaper operating costs, recovery of valuable by-products, or as a result of changing economic factors, such as transportation and raw material costs.

RESERVES

The Bureau of Mines estimated Arkansas reserves of bauxite on an unmined, undried basis to be 49 million tons as of January 1944. During 1944 and 1945 the Bureau's drilling program developed approximately 12 million tons of new reserves, which increased the total for Arkansas to 61 million tons "in place" or about 40 million tons on a mined and dried basis. Subtraction of the 12 million tons mined between the beginning of 1944 and the close of 1951 left a remainder

Digitized by Google

of 28 million tons. None of the foregoing figures included discoveries by private companies since 1944; moreover, new techniques of mining and the increasing use of the Bayer-sinter process to produce alumina may permit inclusion of ore deposits previously considered marginal or uneconomic. The Bauxite chapter of Minerals Yearbook, 1950, cited numerous references on bauxite reserves in the United States and discussed the estimates in greater detail.

On July 17, 1951, the Defense Minerals Administration amended Mineral Order 5 to include bauxite in the list of minerals on which the Federal Government would help prospectors and mine operators finance the cost of searching for new deposits. The incentive was a Government contribution of 50 percent of the cost of exploration projects, subject to DMA regulations and specified terms of the contracts.

Discovery of a new potential source of alumina in Florida was announced by the Geological Survey.[1]

DOMESTIC PRODUCTION

The production of bauxite in the United States increased 39 percent over 1950 to a rate surpassed only during the war years 1942–44. Despite the increase, domestic output comprised only 40 percent of the total new supply as determined by adding imports to production.

TABLE 2.—Production of bauxite in the United States, 1947–51, by quarter years, in long tons [1]

[Dried-bauxite equivalent]

Quarter ended—	1947	1948	1949	1950	1951
March 31	323, 180	295, 488	320, 157	322, 006	378, 031

December 31	294, 649	364, 919	325, 686	350, 541	514, 993
Total	1, 202, 055	1, 457, 148	1, 148, 792	1, 334, 527	1, 848, 676

[1] Quarterly figures adjusted to final annual totals.

Table 3 contains data, by States, on bauxite production and shipments to consumers from mines and processing plants. "Processing plants" include plants engaged in drying, calcining, and activating bauxite but exclude consuming plants which produce alumina, crude aluminum oxide abrasives, or other products not identified as bauxite. Data on total shipments from mines, which were shown in Bauxite chapters of previous Minerals Yearbooks, were excluded from this chapter because they approximated production and were not considered significant. The table on shipments to consumers, by consuming industries, which had been given in previous Bauxite chapters to indicate consumption, was also omitted from this chapter because data on actual consumption have become available for a sufficient number of years.

Alabama.—Bauxite production in Alabama, all mined in the Eufaula district, doubled that of 1950. The Alcoa Mining Co. operated a drying plant in this area, but the only other operator—D. M. Wilson

[1] Ore shipped to producers' processing plants is excluded; dried, calcined, and activated bauxite shipped from these plants is included. Not comparable with shipments shown in corresponding table in 1950 Bauxite chapter.
[2] Computed from selling prices and values assigned by producers.
[3] Production in Virginia ceased in 1946. Bauxite was processed in Florida in 1947–49.

Bauxite Co.—shipped its ore in crude form. The entire output was chemical- and refractory-grade ore averaging approximately 15 percent SiO_2.

Arkansas.—The bauxite-mining district south and southwest of Little Rock, Ark., produced 98 percent of the national output in 1951. Most of the ore was mined in Saline County and the remainder in Pulaski County. Production by strip mining has increased in Arkansas since 1949, while the quantities mined by underground methods remained virtually the same. Consequently, the proportion from underground mines declined from an estimated 29 percent to 17 percent over the 3-year period.

The Alcoa Mining Co. was the largest producer of domestic bauxite in 1951. Most of the ore was dried at its plant in Saline County and shipped to the East St. Louis, Ill., alumina plant. Smaller quantities

TABLE 4.—Recovery of processed bauxite in the United States, 1947–51, in long tons

Year	Crude ore treated	Processed bauxite recovered			
		Dried	Calcined or activated	Total	
				As recovered	Dried bauxite equivalent
1947	655,702	410,727	102,320	513,047	564,829

were used in the chemical and cement industries. Alcoa's mill in Pulaski County calcined bauxite, which was sold chiefly for use in the manufacture of abrasives. The Reynolds Mining Corp., the second-largest domestic bauxite producer, mined in Saline County exclusively. All of its shipments were in crude form to the parent aluminum firm, Reynolds Metals Co.

The Dixon pit and the 400 B. C. mines of the Dulin Bauxite Co. and the Ratcliffe pit of the affiliated Riffe Construction Co. were active bauxite producers during 1951. Although the largest part of the production was shipped undried to a local alumina plant, Dulin also calcined ore for the abrasives industry.

The Berry-Mahan, Rauch Lease, Lewis, and Heckler surface mines near Berger, Pulaski County, were operated by the American Cyanamid Co. in 1951. Most of the ore was treated at the company drying plant before shipment to chemical and oil-refining plants. Consolidated Chemical Industries, Inc., had not mined bauxite since 1948; however, deliveries of high-silica ore were made in 1951 from mine inventories to its concentrating plant. This bauxite eventually was used in the production of aluminum sulfates. The underground Young mine was operated by the Crouch Mining Co. in conjunction with a calcining kiln in Saline County. The Norton Co. continued stripping for abrasive-grade bauxite in the southern part of the Arkansas district during 1951. Calcined ore was shipped to the company abrasives plants. Activated bauxite was produced from purchased ore by the Porocel Corp. Sales of the finished material were made to the oil industry.

Georgia.—The American Cyanamid Co. remained the only bauxite producer in Georgia throughout 1951. Chemical-grade ore was mined at the Fountain and Julia mines, Bartow County, in the northern part of the State, and at the Lane McMicheal mine, Macon County, and processed at the Halls Station drying plant in Bartow County.

CONSUMPTION AND USES

The needs of the rearmament program were reflected in the bauxite industry in 1951 as consumption rose 19 percent over 1950 to reach the highest level in 7 years. All bauxite-consuming industries used more ore than in 1950, but most of the increase in tonnage consumed went into the production of alumina, which was ultimately reduced to aluminum. Expansion plans announced by the primary aluminum producers indicated that the trend for larger consumption by the metallurgical industry would continue for at least 3 more years.

Consumption on an "as-received" basis was 4,005,879 tons, consisting of 1,185,231 tons of crude bauxite, 2,606,882 tons of dried bauxite, and 213,766 tons of calcined and activated bauxite. Bauxite entering the National Stockpile was not included in consumption data.

Alumina.—The plants at Mobile, Ala., East St. Louis, Ill., Hurricane Creek, Ark., and Baton Rouge, La., had a combined production of 1,832,000 short tons of alumina in 1951. On a weighted-average dry-bauxite basis, these plants required about 1.84 long tons of ore per short ton of alumina. Approximately 93 percent of the total United States production, excluding alumina scale and similar byproducts, was calcined alumina, 6 percent alumina trihydrate, and the remainder alumina in tabular, activated, and other forms.

[1] Includes consumption by Canadian abrasives industry.
[2] Revised figure.

An estimated 96 percent of the calcined alumina was consumed at the 12 primary aluminum plants in operation during 1951. The largest other use was in the production of white artificial abrasives. Alumina trihydrate or aluminum hydroxide was used principally in the production of chemicals, including fluoride fluxes for aluminum reduction plants.

The increased consumption of bauxite at alumina plants was uninterrupted since 1946. During 1951 the three primary aluminum producers were enlarging alumina capacity to meet the requirements from the expanding aluminum industry. The Government, acting under authority of the Defense Production Act of 1950 (Public Law 774), approved accelerated amortization for tax purposes on construction for six alumina plants. On completion these plants were to be able to provide 3,437,000 tons of alumina per year.

Aluminum Ore Co. was increasing capacity at both its Mobile, Ala., and East St. Louis, Ill., plants during 1951. It also began construction of a new plant near Bauxite, Ark., which would be able to treat high-silica Arkansas bauxite by the combination Bayer-sinter process. Reynolds Metals Co. was increasing the capacity of its combination-type plant at Hurricane Creek, Ark., and equipping it to operate partly on Jamaican ore. Reynolds also announced that it would construct a new plant near Corpus Christi, Tex., to process Jamaican bauxite exclusively. Kaiser Aluminum & Chemical Corp. was increasing its alumina capacity at Baton Rouge, La., and planned to install facilities to treat Jamaican ore. Although all of the plants were to be able to make alumina from Arkansas, Jamaica, or Guiana bauxite, maximum efficiency is attained by designing plant facilities to treat specific ores. All six plants were to recover alumina by variations of the Bayer process; but the term "combination process" has been applied to methods which include sintering of the red mud from high-silica bauxite, and the term "modified Bayer process" has been used to distinguish the technique for treating Jamaican ore.

Abrasive.—Producers of aluminous abrasives in the United States and Canada increased their consumption of calcined bauxite 56 percent in 1951. The gain, which reflected demand from many industries, was attributed to a general increase in industrial activity resulting from the rearmament program. Since most of the crude aluminum oxide abrasive produced in Canada was returned to the United States for manufacture and consumption of the final product, Canadian bauxite consumption was included in the data for abrasives. Figures

Digitized by Google

for bauxite converted to alumina before the manufacture of special white abrasives are included with alumina in table 5.

Chemical.—In addition to large quantities of alumina, the chemical industry used directly about 4 percent of the bauxite consumed during 1951. The data for the chemical industry in table 5 include bauxite used by municipal water-treatment plants.

TABLE 6.—Production and shipments of selected aluminum salts in the United States, 1950–51

Type of salt	1950				1951			
	Production (short tons)	Shipments [1]			Production (short tons)	Shipments [1]		
		Shippers	Short tons	Value		Shippers	Short tons	Value
Aluminum sulfate:								
Ammonium	700,633	2	680,958	$20,463,473	4,582	3	4,566	$404,231

Total	812,822	[2] 36	794,796	30,929,690	868,958	[2] 37	862,056	38,769,893

[1] Shipped or used by producers.
[2] A company shipping or using more than 1 kind of salt is counted but once in arriving at total.

Bauxite was the largest source of aluminum for the salts production shown in table 6, but about 97,000 short tons of clay, 24,000 tons of commercial aluminum trihydrate, 11,000 tons of secondary aluminum, and small quantities of other aluminum-bearing materials were also used in 1951. Important changes in the production of aluminum salts included increases in sodium, iron-free, and commercial-grade aluminum sulfate.

Refractory.—In 1951 the refractory industry used nearly 50 percent more bauxite than in the preceding year and reported that over two-thirds of the material was foreign in origin. It was anticipated that even greater tonnages of this specially calcined bauxite would be used in high-temperature refractories in future.

Other Industries.—Other bauxite consumers depended chiefly on domestic ore supplies. In this category the manufacture of calcium aluminate cement was the predominate use. Many companies in the oil and natural-gas industries and several producers of ferrous metals used bauxite in 1951, but their combined consumption was less than 1 percent of the total.

STOCKS

Total stocks of bauxite on December 31, 1951, were 7 percent greater than at the end of the preceding year, despite withdrawals from the stockpiles near the Hurricane Creek, Ark., alumina plant. The General Services Administration reported that 365,706 long tons (crude bauxite converted to a dry equivalent tonnage) were sold to the Reynolds Metals Co. in 1951 from stockpiles accumulated during World War II for use at the Hurricane Creek plant. After calculation

Digitized by Google

to convert bauxite in various degrees of processing to a dried-equivalent basis, it was noted that consumers' inventories increased about 34 percent during 1951, while those at mines and processing plants were 85 percent greater.

TABLE 7.—Stocks of bauxite in the United States December 31, 1947–51, in long tons

Year	Producers and processors		Consumers		Government, crude [1]	Total [1]	
	Crude	Processed [2]	Crude	Processed [2]		Crude and processed [2]	Dried-bauxite equivalent
1947	560,967	11,497	35,983	399,224	3,277,090	4,284,761	3,724,759
1948	654,601	7,441	57,191	590,124	3,277,090	4,586,447	4,023,300
1949	574,983	8,467	34,183	832,083	3,277,090	4,726,806	4,184,786

1951	890,336	18,552	44,169	1,008,767	2,630,792	4,592,616	4,069,796

[1] Excludes National Stockpile.
[2] Dried, calcined, activated, and sintered.
[3] Revised figures.

All inventory data presented in this chapter exclude bauxite in the National Strategic Stockpile. During 1951 both metal-grade and refractory-grade bauxite were on the Government's purchase list of strategic materials for this stockpile.

TABLE 8.—Chemical analysis in bauxite purchase specifications used for the National Stockpile during 1951

[Percent by weight]

	Metal grade, dry basis	Refractory grade, calcined basis
Alumina (Al_2O_3)	55.0 minimum	85.0 minimum.
Silica (SiO_2)	5.0 maximum	7.0 maximum.
Alkalies (as oxides)	1.0 maximum	Not specified.
Ferrous iron (as FeO)	3.0 maximum	Do.
Ferric iron (as Fe_2O_3)	Not specified	3.75 maximum.
Phosphorus (as P_2O_5)	1.0 maximum	Not specified.
Manganese, chromium, and vanadium (as MnO_2, Cr_2O_3, and V_2O_5).	2.0 maximum	Do.
Titania (TiO_2)	Not specified	3.75 maximum.
Loss on ignition	50% of Al_2O_3 minimum.	.5 maximum.

PRICES

The average value of crude bauxite shipped from domestic mines to consumers and processing plants, as estimated from company reports, was $5.67 per long ton in 1951. Average values for processed ore, f. o. b. producing plants, were $7.71 per long ton of dried bauxite, $17.32 per ton of calcined bauxite, and $63.23 per ton of activated bauxite. Since the values of large quantities of bauxite were assigned to tonnages produced for consumption by the producer or an affiliate, average prices could not be considered as exact costs to purchasers on the open market. Furthermore, prices of bauxite in all states of processing depended upon the grade of each shipment, which was determined largely by chemical analysis.

Market quotations published in E&MJ Metal and Mineral Markets were as follows throughout 1951: Domestic ore, chemical, crushed and

Digitized by Google

dried, 55 to 58 percent Al_2O_3, 1.5 to 2.5 percent Fe_2O_3, $8 to $8.50 f. o. b. Alabama and Arkansas mines; other grades, 56 to 59 percent Al_2O_3, 5 to 8 percent SiO_2, $8 to $8.50, f. o. b. Arkansas mines; pulverized and dried, 56 to 59 percent Al_2O_3, 8 to 12 percent SiO_2, $14 to $16, f. o. b. Arkansas mines; abrasive grade, crushed and calcined, 80 to 84 percent Al_2O_3, $17, f. o. b. Arkansas mines; crude (not dried) 50 to 52 percent (Al_2O_3 on dry basis), $4.50 to $5.50, f. o. b. Arkansas mines.

The average price of the crude bauxite from the Hurricane Creek stockpiles sold to the Reynolds Metals Co. by General Services Administration during 1951, calculated on a long dry ton equivalent basis, was $6.67. Dry samples analyzed 51 percent Al_2O_3, 11 percent SiO_2, and 4 percent FeO.

Market price quotations for aluminum compounds were published in Oil, Paint and Drug Reporter and Paint, Oil and Chemical Review. The average value of aluminum sulfate, the leading aluminum salt produced, was 1.5 cents per pound.

FOREIGN TRADE[2]

United States imports of crude and dried bauxite increased 12 percent during 1951. Preparations for large-scale mining in Jamaica and increased production in the Guianas, which were being made by subsidiaries of all three American aluminum producers, foretold continuation of increasing dependence on foreign bauxite. Imports had exceeded domestic output since 1947 and were expected to be twice the domestic rate of production by the end of 1952.

Surinam, from which 2,318,917 long tons (as shipped) was received, was the largest supplier and provided most of the increase in imports during 1951. Indonesia shipped 365,309 tons, British Guiana 127,477 tons, and Trinidad (probably all South American ore) 18,226 tons. Bauxite totaling 1,712,737 tons entered the United States through the Mobile customs district, 1,021,060 tons through New Orleans, and the remainder through 8 other districts. Nearly all of the alumina and over half of the other aluminum compounds imported in 1951 came from Canada.

TABLE 9.—Bauxite and aluminum compounds imported for consumption in the United States, 1947–51

[U. S. Department of Commerce]

Year	Bauxite (crude and dried)[1]		Alumina		Aluminum compounds	
	As imported (long tons)	Value	Short tons	Value	Short tons	Value
1947	1,821,580	$11,869,631	----------	----------	80	$2,348
1948	2,488,915	15,820,743	6	$3,547	5,559	124,167
1949	2,688,164	16,353,298	175	19,192	1,472	46,736
1950	[3] 2,516,247	[3] 15,729,855	218	20,038	3,113	126,715
1951	2,829,929	17,862,887	965	88,135	5,334	275,238

[1] Only small quantities of undried bauxite were imported. Complete data on imports of calcined bauxite were not available. Beginning September 1950, calcined bauxite for refractory uses only was imported as follows: 1950, 9 tons ($329); 1951, 18,642 tons ($405,438).
[2] Revised figure.

[2] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Digitized by Google

Duties on imports remained unchanged throughout 1951 as follows: Crude and dried bauxite, 50 cents per long ton; calcined bauxite for use in the manufacture of refractories, $1 per long ton; other calcined bauxite, 15 percent ad valorem; alumina and refined aluminum hydroxide, ¼ cent per pound.

Exports of bauxite, virtually all of which were shipped to Canada, nearly doubled in 1951. Most of the 71,313 long tons, classified as bauxite and other aluminum ores, was calcined bauxite, and 18,635 tons were classified as bauxite concentrates, alumina included. Colombia was the chief recipient of the aluminum sulfate exported, while Canada and Mexico received most of the other aluminum compounds.

TABLE 10.—Bauxite and aluminum compounds exported from the United States, 1947–51

[U. S. Department of Commerce]

Year	Bauxite (including bauxite concentrates), long tons			Aluminum sulfate		Other aluminum compounds	
	As exported	Dried bauxite equivalent [1]	Value	Short tons	Value	Short tons	Value
1947	94,369	141,235	$1,888,040	23,389	$706,572	3,753	$738,374
1948	54,113	86,284	1,202,036	14,342	467,622	3,539	599,210

[1] Calculated by Bureau of Mines.
[2] Revised figure.

WORLD REVIEW

Estimates of total world bauxite reserves ranged from 1.2 to 1.6 billion tons. The combined reserves of the Guianas, the Caribbean Islands, and the United States were about one-half billion tons. The rate of bauxite discoveries on a worldwide basis has historically exceeded depletion; but the increasing rate of bauxite mining, as shown in table 12, has tended to narrow the difference.

TABLE 11.—Past, present, and potential bauxite-producing countries, in order of quantities mined and estimated reserves

Rank	Total production, 1900–50	Production 1951	Estimated reserves
1	United States	Surinam	Jamaica.
2	France	British Guiana	Hungary.
3	Surinam	United States	Gold Coast.
4	British Guiana	France	Brazil.
5	Hungary	U. S. S. R.	Yugoslavia.
6	U. S. S. R.	Indonesia	British Guiana.
7	Italy	Yugoslavia	Greece.
8	Yugoslavia	Hungary	France.
9	Indonesia	Greece	Surinam.
10	Gold Coast	Italy	China.

The world production in 1951 gained 31 percent over 1950, as all major bauxite-producing countries reported increased activity. Production in the Western Hemisphere was 62 percent of the total—approximately the same proportion as in other recent years. Out-

Digitized by Google

put in the U. S. S. R. and satellite countries was 11 percent, and other countries, principally France, Indonesia, Yugoslavia, Greece, Italy, and Gold Coast, provided the remaining 27 percent.

[4] Negligible.
[5] Exports.

British Guiana.—Bauxite production in British Guiana in 1951 increased 26 percent to surpass 2 million tons for the first time. All of the colony's production was exported; approximately 90 percent was shipped to Canada, 8 percent to the United States, and most of the remainder to United Kingdom. The Demerara Bauxite Co., an affiliate of the Aluminum Co. of Canada, Ltd., was reported to have placed in operation a new drying kiln of 400,000 tons annual capacity. A second new kiln, under construction, was to produce a supercalcined refractory-grade bauxite. It was expected that a large portion of the calcined ore would be shipped to the United States.

France.[3]—Recent estimates of bauxite reserves in France, the largest European producer, have ranged from 30 million tons to over 100 million tons. The alumina in the bauxite occurs principally as the monohydrate mineral, boehmite. While bauxite is found in many Provinces of France, Var and Hérault have been the leading producers. In 1951 French production increased 40 percent to the highest level in that nation's long record as a bauxite producer. Since 1939 mechanization has doubled the production per miner. One of the reasons for the gain in output was the increasing demand from the French aluminum industry, resulting from a greater availability of power for metal production. However, the excess mining potential has made France an important supplier for foreign markets. In 1950 about 135,000 metric tons was exported to Western Germany, 71,000

[3] Bureau of Mines, Mineral Trade Notes: Vol. 33, No. 4, October 1951, pp. 3–6

Digitized by Google

tons to United Kingdom, and 18,000 tons to other European countries. Toulon, which was to have its bauxite loading capacity expanded, was the chief port from which shipments were made in 1951, but much ore was sent to Germany by rail.

The price of French bauxite in June 1951, as established by Government decree, was 1,074 francs (official exchange rate, 350 francs—$US 1.00) per metric ton, f. o. b. mines. This rate applied to red, metal-grade bauxite analyzing 55 percent Al_2O_3 and 5 percent SiO_2. Premiums of 45 francs per ton for each percent Al_2O_3 over 55 and 135 francs per ton for each percent of SiO_2 under 5 were granted. The average selling price was approximately 1,300 francs. Prices for gray, abrasive-grade bauxite and white, refractory-grade bauxite were given as 1,800 to 2,500 francs per ton and 2,500 to 5,000 francs per ton, respectively.

French West Africa.—The Société des bauxites du Midi installed equipment for the commercial production of bauxite on the Island of Kassa off the French Guinea coast of French West Africa. Dried ore was to be shipped, mostly to Canada, at the rate of 300,000 to 400,000 metric tons annually beginning late in 1952. The more extensive ore deposits on the mainland in the Boffa-Boké region and on the Konkouré River also attracted attention because of the great hydroelectric potential in these areas.

Greece.—Greece more than doubled its bauxite production in 1951 and regained the importance it held as an exporter immediately before World War II. Further increases were foretold at the close of the year through announcement of a contract between the United States Mutual Security Agency and the Eleusis Bauxite Mines. Funds advanced to the Greek company for mining equipment and working capital were to be repaid by delivery of 450,000 metric tons of bauxite to the United States Government. It was planned to have this bauxite converted to aluminum for the National Stockpile by two German producers.

Hungary.—The bauxite reserves in Hungary are the largest known in Europe. Before World War II virtually all of the mine production was exported. Completion of the Almásfüzitó alumina plant in 1951, however, was a significant step in the country's plan to process its own ore. It was reported that the plant was designed for a subsequent expansion that would make it the largest alumina plant in Europe.[4]

Italy.—The reserves of bauxite in Italy have been estimated at 11 million tons, most of which are located in the southern end of the Italian Peninsula. Although production gained and imports declined in 1951, nearly one-third of the new supply came from Yugoslavia. Alumina production increased substantially as Italy continued to meet domestic requirements and to export to Switzerland and Austria.

Jamaica.—The greatest development of bauxite-producing facilities in the world in 1951 was under way on the Island of Jamaica, as three mining companies—subsidiaries of North American aluminum producers—prepared to mine from ore deposits discovered there since 1942. Numerous articles appeared in the press, describing the

[4] Light Metals, Exploitation of Bauxite in Hungary: Vol. 15, No. 166, January 1952, pp. 9-11.

Digitized by Google

thorough planning and well-integrated construction of the open-pit mining, processing, transportation, housing, and other facilities of all three companies.[5]

Reynolds Jamaica Mines, Ltd., was expected to be the first to produce, with shipments beginning in mid-1952. An agreement reached in 1951 provided that the Economic Cooperation Administration advance Reynolds $2,284,000 in addition to previous ECA loans. The new funds, to be supplemented by Reynolds, were to expand facilities previously planned. According to plans, Reynolds would eventually produce 750,000 to 1 million tons per year.

The Kaiser Bauxite Co. expected to begin a 1-million-ton-per-year mining operation in Jamaica on completion of its facilities late in 1952. A new railway was under construction to haul ore to the drying plant, storage bins, and port at Little Pedro on the southern coast.

The third company, Jamaica Bauxites, Ltd., a subsidiary of Aluminium, Ltd. was the only company that planned to mine bauxite and also produce alumina in Jamaica.[6] Facilities for producing 450 metric tons of alumina per day were under construction near Mandeville, Manchester Parish. It was anticipated that the plant would ultimately be expanded to a capacity of 670 tons. Alumina was to be shipped from a new pier at Old Harbour Bay on the southern coast and consumed largely at the new reduction plant of the parent company in British Columbia, Canada.

Malaya.—Bauxite mined during the Japanese occupation of Malaya was exported to Japan during 1951. Several companies had shown an interest in the deposits in southern Jahore, and mining may be resumed in 1952.

Surinam.—Although there were reports that several foreign companies and the colony's mining bureau were conducting new bauxite investigations in Surinam, the world's largest bauxite producer in 1951, only two companies actually mined the ore. Of the total production (which included 62,000 metric tons of abrasive ore and 54,000 tons of chemical-grade bauxite) the Surinam Bauxite Co. produced 2,184,000 tons and the N. V. Billiton Co. 487,000 tons. All bauxite mined in Surinam during 1951 was exported, and the United States received approximately 96 percent. The Surinam Bauxite Co., a subsidiary of the Aluminum Co. of America, was engaged in opening the Rickanau Hill deposit north of the exhausted Moengo mines and the Rorac deposit about 5 miles north of the Paranam operations. Both companies planned increases in kiln capacity.

U. S. S. R.[7]—Official U. S. S. R. statistics on the 1951 production of bauxite, as in the case of most other commodities, were not available Estimates shown in table 12 were based largely on estimates of aluminum production. It is believed that most of the aluminum was produced from domestic bauxite, but significant allowances were made for production from imported bauxite, nephelite, and alunite.

Venezuela.—The Venezuelan Government announced that bauxite had been discovered near Upata, in Estado Bolivar. Estimates ranging up to 2 million tons of high-grade ore were reported.

Beryllium

By Stanley Needleman

GENERAL SUMMARY

MILITARY and essential civilian demands for beryllium products, particularly beryllium-copper, exceeded the beryl supply available to consumers during 1951. The situation was most critical at midyear because of the export restrictions placed upon beryl exports by Brazil from January 1 to July 16, 1951. A total supply of 4,800 short tons of beryl was available in the United States; of this amount, 484 tons was produced from domestic mines, and 4,316 tons was imported. Commercial beryl usually contains 10 to 12 percent beryllium oxide.

Concern over the beryl supply caused industry and Government groups to convene for study of the situation. Attention was directed to low-grade domestic deposits, especially with reference to developing suitable mining and milling methods. Beryl has been included in Group I of the Munitions Board list of critical and strategic materials to be acquired for the National Stockpile. To prevent curtailment in the output of beryllium products, beryl was exempted from price control by the Office of Price Stabilization under Regulation 9, Amendment 4, effective August 10, 1951.

The Defense Minerals Administration, succeeded by the Defense Minerals Exploration Administration and the Defense Materials Procurement Agency under authority of the Defense Production Act of 1950, actively participated in an effort to improve the domestic beryl situation. Government subsidies stimulated interest in domestic deposits formerly considered uneconomic.

TABLE 1.—Salient statistics of beryllium concentrates (beryl) in the United States, 1936–51, in short tons

Year	Domestic production [1] [2]	Imports for consumption	Exports		Consumption [3]	Average price per unit BeO		World production [2]

RESERVES

World reserves of recoverable beryl, excluding satellite nations of the Soviet Union, have been estimated at about 250,000 short tons.

Estimates of potential beryl reserves in Canada have been made only for Manitoba, Ontario, and the Northwest Territories; further detailed geologic study of Canadian pegmatites may add appreciably to this knowledge.

Domestic reserves in South Dakota, New Hampshire, Colorado, Maine, and North Carolina total about 25,000 short tons. Reserves have been increased with the introduction of recently developed techniques for utilizing low-grade ores.

Most of South Dakota's beryl reserves are in the southern Black Hills, in Pennington and Custer Counties. Pegmatites in the Black Hills area have been estimated to contain 11,824 short tons of beryl; according to the Geological Survey, 2,636 tons can be recovered by hand sorting. Measured reserves total about 234 tons. The major reserves occur in the Keystone, Custer-Pringle, and Hill City districts.

A survey of the New England pegmatites has been conducted by the Bureau of Mines since 1949. This is part of an overall program to increase beryl production by developing low-grade deposits. Substantial tonnages of pegmatite reserves were indicated as a result of the drilling portion of the survey.

Low-grade beryl deposits also have been found in North Carolina, Colorado, Utah, Idaho, South Dakota, Wyoming, New Mexico, Arizona, California, and the New England States.

DOMESTIC PRODUCTION

MINE PRODUCTION

Domestic production of beryl during 1951 was 484 short tons, over 13 percent less than the record output of 1950. The Harding mine, near Dixon, N. Mex., was again the largest individual beryl producer; an output of about 140 tons was attained. As a result, New Mexico continued to lead the States in beryl production, followed closely by South Dakota. Other producing States, in order of importance, were Colorado, New Hampshire, Maine, Arizona, and North Carolina. Beryl production in the Black Hills area of South Dakota was reported by Keystone Feldspar & Chemical Co. (Peerless mine), J. A. Johnson (Big Chief claims), Howard L. Peterson (Hugo and Etta mines), and Lawrence A. Sears (Johnson mine), all near Keystone, and Walter Clifford, George C. Bland (Beecher mine), John D. Fisher, and Francis Michaud (The Mick), near Custer. Principal Colorado production came from the Beryllium Mining Co. (New Anniversary claims) near Ohio City, Gunnison County; Nelson-Hermstein Mining & Developing Co. (Devil's Hole mine), near Canon City, Fremont County; and Consolidated Feldspar Corp. (various unspecified properties). Shipments were reported in 1951 from New Hampshire by Whitehall Mining Co., Ruggles quarry, near Grafton.

Average value per ton	$157.26	$177.87	$173.89	$268.69	$321.02	$305.10	$333.36

[1] Included with "Other," to avoid disclosure of individual company operations.
[2] Revised figure.
[3] Includes States indicated by footnote reference 1; in addition, 1947, Connecticut and Maine; 1948, Maine; 1949, Arizona, Maine, and North Carolina; 1950, Arizona and Maine; 1951, Arizona, Maine, and North Carolina.

A deposit of helvite (sulfosilicate of manganese, iron, and beryllium) at Iron Mountain, N. Mex., has remained undeveloped mainly because of difficulties encountered in producing a suitable concentrate economically.

REFINERY PRODUCTION

Beryllium Corp., Reading, Pa., consumed beryl to produce beryllium-copper master alloy (4 percent Be); beryllium-aluminum master alloy (5 percent Be); beryllium-nickel (2.7 percent Be); and beryllium-copper alloys (0.25–2.85 percent Be) in the form of sheet, strip, rod, wire, castings, and safety tools. Brush Beryllium Co., Cleveland and Luckey, Ohio, continued to produce beryllium metal and oxide and other beryllium products, principally for the Atomic Energy Commission. The company obtained $800,000 from the Reconstruction Finance Corp. to construct a new plant, 18 miles west of Luckey, Ohio, midway between Elmore and Oak Harbor, in which the company was to resume production of beryllium-copper master alloy. Operations were expected to begin late in 1952.

Clifton Products Inc., Painesville, Ohio, inactive in commercial production of beryllium since early 1949, produced some beryllium products for special uses and intensified efforts in the field of beryllium research.

Beryl Ores Co., Arvada, Colo., continued to beneficiate low-grade ore (some as low as 2.5 percent BeO) and to grind beryl for use in the ceramic industry; the ore is purchased from other producers. The company reportedly produced a small quantity of beryllium oxide.[1]

The Champion Spark Plug Co., Toledo, Ohio, and Detroit, Mich., and A. O. Smith Co., Milwaukee, Wis., consumed beryl for ceramic materials. The Foote Mineral Co., Philadelphia, Pa., continued to grind and blend beryl for the ceramic industry.

CONSUMPTION AND USES

Consumption of beryl in 1951 for the production of metal, alloys, and compounds continued at a high level. Consumers relied upon their own stocks during the first half of the year because of Brazilian

[1] E&MJ Metal and Mineral Markets, vol. 152, No. 7, July 1951, p. 162.

Digitized by Google

export limitations. The problem of meeting the growing military and civilian demands, especially for beryllium-copper, was made less acute by the development of new alloys containing smaller percentages of beryllium and by substituting beryllium-free materials for certain less critical uses.

Industrial research on beryllium alloys resulted in the development and introduction to the trade of a new copper-base alloy containing less than 2 percent beryllium. This new alloy is an effective substitute for the conventional beryllium-copper alloy (2 percent Be) in many applications. Through its use, the available supply of beryllium was significantly extended. An aluminum alloy containing a high percentage of beryllium was introduced to the trade for special defense applications in photographic and aircraft equipment.

Beryllium's most important commercial applications are as an alloying agent with copper and as metal, oxide, and other compounds. Beryllium-copper alloys, containing 0.15 to 2.85 percent beryllium, have many important metallurgical applications, military and civilian. This wide utilization is possible because of their adaptability to heat treatment, high strength (tensile and fatigue), corrosion and wear resistance, hardness, high conductivity (electrical and thermal), low creep tendency, and nonmagnetic and nonsparking properties. Beryllium-copper alloys are now being used in aircraft, guided missiles, weapons, electronics, construction equipment, ships, communications, machine tools, and nuclear energy studies.

Patents issued during 1951 included methods for producing beryllium-copper cyclotron target,[2] beryllium-zinc silicate,[3] beryllium-calcium silicate phosphors,[4] and a beryllium-gold alloy for use in neutronic reactors.[5]

STOCKS

During 1951 Government stocks continued to increase through the concerted efforts of various Government agencies to meet the objective of the National Stockpile program.

As a result of the export restriction placed upon beryl by Brazil during the first half of 1951, industrial inventories were depleted temporarily because domestic production and imports from other sources could not meet requirements. At the end of 1951 industry stocks of beryllium metal, alloys, and compounds were about the same as reported at the end of 1950. Statistics covering these stocks are not available for publication.

PRICES

E&MJ Metal and Mineral Markets quoted domestic beryl ore, per unit BeO, 10–12 percent BeO, f. o. b. mine, as follows: Colorado, nominal throughout 1951; North Carolina, January 11, $26–$28; March 1, $28–$30; July 5, $32–$34; August 23, $33–$37; and unchanged thereafter. Quotations for the same grade of imported ore,

[2] Hamilton, J. G., Putnam, T. M., and Wiens, J. B. (assigned to Atomic Energy Commission), Beryllium Target and Method of Manufacture: U. S. Patent 2,549,596, Apr. 17, 1951.
[3] Roos, Jacob (assigned to General Electric Co.), Preparation of Zinc-Beryllium Silicate Phosphors: U. S. Patent 2,542,260, Feb. 20, 1951.

c. i. f. United States ports, were: February 15, $28; July 5, $32 August 16, $33–$36.50; and unchanged thereafter.

On November 15, 1950, the beryllium industry had changed the beryllium-copper pricing policy by beginning to quote the master alloy (4 percent Be average content) in terms of alloy instead of contained beryllium. The master alloy remained unchanged during 1951 at $1.56 per pound of alloy ($30–$32 per pound of contained beryllium). Beryllium-magnesium-aluminum (5 percent Be) and beryllium-aluminum (5 percent Be) master alloys were quoted at $55 and $69 per pound of contained beryllium, respectively. Beryllium-nickel (2.7 percent Be and 1 percent Cr) was quoted at $2.70 per pound of alloy. Quoted prices for beryllium-metal powder, standard mesh, per pound, were: $95, technical grade; and $103, premium grade.

High-fired refractory-grade beryllium oxide was quoted at $15–$18 per pound, depending upon quantity. Beryllium nitrate was offered at $3.95–$5.00 per pound, depending upon quantity.

Prices quoted for beryllium metal, lump or pebble size, per pound were: $56.96–$71.50, technical grade; and $104.50, premium grade.

FOREIGN TRADE [6]

Imports of 4,316 short tons of beryl into the United States during 1951 were about 11 percent less than the record high of 4,860 tons (revised) received in 1950. The Union of South Africa was the principal source, furnishing about 40 percent of total imports; Brazil, the second important source, contributed about 25 percent. Significant amounts were received also from Southern Rhodesia, India, Mozambique, and Portugal.

The United States also imported 30,110 pounds of a product containing beryllium oxide and beryllium carbonate from Italy and 17 pounds of beryllium carbonate from Canada. The material from Italy represented reshipment of processed old stocks purchased by the Italians from Brazil and Argentina before World War II.

Exports of beryllium metal, alloys, and scrap from the United States during 1951 totaled 189,513 pounds, valued at $309,830. The recipients were: United Kingdom, 97,904 pounds; Canada, 59,775 pounds; Sweden, 11,009 pounds; Western Germany, 6,497 pounds; Australia, 5,069 pounds; Argentina, 3,438 pounds; Greece, 2,606 pounds; Belgium, 1,320 pounds; with the balance of 1,895 pounds distributed among six other countries. Exports of beryl totaled 504 pounds, valued at $1,053; Canada was the recipient.

Beryllium ore, metal, alloys, compounds, and scrap remained on the list of products requiring licenses for export from the United States, in accordance with the directive of the Office of International Trade of the United States Department of Commerce that became effective on July 16, 1948. No license was necessary for materials shipped to Canada.

TECHNOLOGY

Investigations of metallurgical and technologic problems involving beryllium metal, alloys, and compounds were continued by interested Government agencies, industry, research institutions, and universities because of the metal's strategic and industrial importance. New techniques were developed in the production of beryllium-copper castings.[7]

The Bureau of Mines continued research to develop a satisfactory and economical method for recovering beryl and other important associated minerals from pegmatites. Research on beneficiating low-grade beryl ore met with some success; a flotation method was developed on a laboratory scale. Investigations were made to determine the most efficient and economical method of mining pegmatites.

WORLD REVIEW

Afghanistan.—Afghanistan first reported beryl production in 1950. According to unconfirmed reports, about 2 metric tons of beryl was

[7] Richards, John T., Beryllium-Copper Parts Designed for Investment Casting: Am. Machinist, vol. 95, No. 28, July 14, 1951, pp. 1046–1049. Beryllium-Copper Sand Castings: Foundry, vol. 79, No. 8, August 1951, pp. 90–256.

Digitized by Google

produced in 1951 from a deposit in the Kunar Valley, north of Jalalabad.

Argentina.—On December 21, 1951, Argentina issued Decree 23,063 transferring complete control of beryl from the Argentine Industrial Credit Bank to the Argentine Trade Promotion Institute. All beryl stocks and contracts were included in the transfer.

On January 10, 1951, the Minister of Industries and Commerce in Argentina announced a stimulating base price of 150 pesos per unit of beryl. The price to producers was 20 pesos per kilogram late in June. The increase was officially attributed to higher mining costs and the prices of the international market. No production statistics for Argentina are available for 1951.

Belgian Congo.—Beryl was reported in the pegmatites of Maniema and Ruanda-Urandi.

Brazil.—Brazil has been the source of most of the world's beryl supply since 1935. Principal producing States have been Paraíba, Rio Grande de Norte, Ceará, and, more recently, Minas Geraes. The bulk of the output has come from about 200 deposits, although as many as 400 are believed to have contributed to the production. Because of transportation difficulties, the commercial possibilities of the known productive areas have not been investigated thoroughly. Records of pegmatite mining in Brazil during World War II have indicated that between 3,000 and 3,500 tons of rock yielded an average

Digitized by Google

of 10 metric tons of beryl and 1 ton of tantalite, at an estimated cost of $1 per metric ton of rock mined. Other deposits have been found in Pernambuco, Bahia, and Gouvernador Valodones.

In July, the Brazilian Government issued a decree limiting the export of beryl to 1,500 metric tons for the second half of 1951 and establishing a minimum price of about $36.50 per metric ton unit on the concentrates.[8]

Negotiations were conducted by American and Brazilian representatives of private companies directed toward the erection of two beryllium oxide processing plants in Brazil. Proberil, a Brazilian company financed with Brazilian and American capital, planned to build an oxide plant near São Paulo.[9]

Canada.—Reports of numerous beryl occurrences in Canada have been published in recent years, but few of these discoveries have developed into large commercial sources. Canadian Beryllium Mines & Alloys, Ltd., shipped 29 short tons of beryl (10 percent BeO) late in October 1950. This ore had been on hand for years and was sold because of prevailing high prices. The company reported 250 short tons of low-grade ore in stock on June 30, 1951; the ore reportedly came from properties in Renfrew County, Ontario.[10]

Beryl occurrences continued to be reported from the Amos Val d'Or area in Figuery Township, Province of Quebec; they appeared to contain isolated beryl crystals in pegmatite dikes. No pockets of any magnitude had been found; however, the size and continuity of the dikes did not preclude the possibility of extensive beryl deposits. Inasmuch as the grade of the ore seemed to be low, such a deposit probably would have to be worked on a large tonnage basis in order to be economical. Beryl occurs, in potentially large quantities, in the Cat Lake-Winnipeg River area, about 90 miles northeast of Winnipeg, Manitoba, near the Ontario boundary.

France.—In recent years France reportedly has been stockpiling beryl for possible use by its Atomic Energy Commission. Sources of the ore are Madagascar, French Morocco, Portugal, Mozambique, South West Africa, Brazil, and India. A small quantity of beryl has been produced in France from a mine near La Vedrenne, north of Limoges.

Pechiney (Compagnie de Produits Chimiques et Électrométallurgiques), formerly known as Alais Frogues et Camargue, has been the only beryl processor in France. The company has two ore-processing plants in the Province of Savoie—one at St. Jean de Maurienne, to produce beryllium-copper alloys; the other at Maurienne, to produce beryllium metal. The company also refines some semiprocessed beryllium-copper master alloy; this source material, in part, is imported by Pechiney from the United Kingdom and produced, in part, by the company itself.

French Morocco.—Mines des Zenaga, in the Anti-Atlas Mountains, reported a production of 75 metric tons of beryl during 1951. A deposit in the Tiznit area, in the extreme southern part of French Morocco, attracted the attention of prospectors and engineers.[11]

Digitized by Google

Germany.—In Western Germany the processing of beryl to produce beryllium metal continued to be prohibited under the terms of an agreement reached by France, the United Kingdom, and the United States. Degussa, in Frankfort, fabricated imported beryllium metal for use in X-ray equipment, and Vacuumschmelze, A. G., formerly Heraeus Vacuumschmelze, A. G., at Hanau, produced beryllium-copper and other beryllium alloys from imported master alloy stock.

India.—India produced 215 metric tons of beryl during 1951; this was the first year since 1946 for which the country released beryl-production statistics. The Indian Atomic Energy Commission was actively guiding research directed toward exploiting the country's mineral resources. Export restrictions were relaxed for the first time since 1946 to allow certain shipments of beryl to the United States for atomic energy projects.[12]

Beryl was recovered as a byproduct from a mica-mining operation at Rajputana.[13] Small quantities of beryl have been produced near Nellore in the State of Madras. Potentially commercial deposits occur in Mysore State and in Madras State, near Saidapuram, Pattalai, Sermattam Palaiyam, and Tittampalaiyam.

Madagascar.—Expanded beryl production in the Fianarantsoa area of Madagascar resulted in a total output of 584 short tons during 1951.

Mozambique.—In Mozambique, Empresa Miniera do Alto Ligonho was the largest producer of beryl during 1951. A small amount was shipped from the Boa Esperanca mine. Beryl occurrences were investigated and developed in the highly kaolinized pegmatites in the Alto Ligonho district, at Muiane, Naipa, Marigue, Nanro, Nahora, Macula, Nahia, and Piteia, and in the Alto Molocue district.

Portugal.—Portugal has commercial beryl deposits near Viseu, in the northeastern section of the country; the output from this area totaled 112 metric tons during 1951. A mine was operated at Mangualde, and interest was shown in a deposit near Vale da Serra. High prices and a steady demand stimulated the increased output of beryl in the country.

Southern Rhodesia.—Southern Rhodesia recorded an output of 1,110 short tons of beryl during 1951 to make the country the leading producer in Africa. Production came principally from deposits in the Gweld and Fort Victoria districts, with smaller amounts from the Salisbury, Mtoko, and Bulawayo districts. Douglas Lawrie, Ltd., at Bikita, 50 miles west of Fort Victoria, accounted for most of the production. At this operation tantalite and lithium minerals are recovered with the beryl. A new occurrence of beryl was reported near the Mititikwe River, 16 miles southeast of Fort Victoria. Recent discoveries in the Miami area disclosed important beryl concentrations in mica pegmatites. Low-grade beryl occurrences were discovered in the Filabusi area of the Bullawayo district.[14]

Digitized by Google

South-West Africa.—The easy-to-mine beryl-bearing alluvial deposits were virtually depleted during 1951. These deposits occur near the pegmatites in the Warmbad district, near the Union of South Africa border, and in the Karabib-Usakos area east of Walvis Bay. The Jooste lithium mine was the principal pegmatite operation in the country.

Uganda.—Beryl production was 2 tons in 1951, compared with 44 tons for 1950. The production during both years came from the Ankole district.

United Kingdom.—In England, Mallory Metallurgical Products, Ltd. (Wembley, Middlesex), Telegraph Construction & Maintenance Co., Ltd. (Greenwich), and the Beryllium Smelting Co., Ltd. (London), produced beryllium alloys from master alloys imported from the United States. Several other British companies seriously considered manufacturing beryllium metal, alloys, and salts because the demand for semifabricated items in the United Kingdom exceeded the supply of master alloy imported from the United States. Plants in the United Kingdom continued to remelt ingots of the master alloy and add metals, such as cobalt, to produce ternary alloys before fabrication into rod, sheet, tube, and wire.[15]

Bismuth

By Abbott Renick

GENERAL SUMMARY

THE DOMESTIC supply[1] of bismuth metal in 1951 decreased 21 percent from that in 1950. In spite of the fact that increased production capacity at principal refineries permitted handling accumulated bismuth-bearing material and treatment of imported bismuth concentrates from Korea, total refinery production of bismuth metal in the United States was 10 percent below that in 1950.

Exports of bismuth metal during 1951 decreased 26 percent from the 1950 figure, and the United Kingdom again received the major portion.

Stocks of metal held by producers were 41 percent higher on December 31, 1951, than at the end of 1950.

Peru continued in 1951 to be the largest foreign producer of refined metal, supplying 86 percent of the total imports into the United States.

The New York market price of metallic bismuth remained through the year at $2.25 per pound in ton lots, unchanged since September 5, 1950.

DOMESTIC PRODUCTION

Most of the bismuth produced in the United States is obtained as a byproduct from smelting domestic and foreign lead ores and from refining imported bismuth bars containing lead as a major impurity. Some bismuth was recovered in 1951 from imported bismuth-bearing tungsten ore. The Bureau of Mines is not at liberty to divulge the quantities produced, but 1951 output increased 33 percent over that in the previous year.

Companies reporting output of refined bismuth metal in 1951 were American Smelting & Refining Co., at Omaha, Nebr., and Perth Amboy, N. J.; Anaconda Copper Mining Co., at Anaconda, Mont.; and U. S. S. Lead Refinery, Inc. (subsidiary of United States Smelting, Refining & Mining Co.), at East Chicago, Ind. The Cerro de Pasco Corp., at its Brooklyn, N. Y. plant, is the principal domestic producer of bismuth alloys; the bismuth metal used is obtained from the company's lead smelter at La Oroya, Peru.

In Alaska, Native Bismuth, Inc., started development work at Charley Creek, approximately 35 miles north of Nome. Bismuth

[1] Opening stocks plus domestic refinery production plus imports minus exports minus year-end stocks.

Digitized by Google

occurs there as native bismuth and bismuthinite in a siliceous gangue material. An energetic development campaign was planned for the 1952 season.[2]

CONSUMPTION AND USES

As a result of the defense program and the continued high-level civilian demand, the requirements for bismuth exceeded the supply during the early part of 1951. Bismuth consumption in the pharmaceutical industry was approximately the same as in 1950. The National Production Authority placed various restrictions on the use of bismuth to conserve supplies. Effective March 9, 1951, Order M–48 restricted the use of bismuth and bismuth alloys to specified processes and purposes. The order set limitations on acceptance of deliveries to 60 percent of the base period established in the first half of 1950, limited inventories to 1 month's requirements, and provided for a set-aside reserve of 20 percent from production and imports. Order M–48 was amended August 10, 1951, so that, effective September 1, 1951, a consumer might accept up to 100 percent of his monthly supply during the base period.

TABLE 1.—Bismuth metal consumed in the United States in 1951, by uses [1]

Use	Pounds	Percent of total
Pharmaceutical	569,600	36
Ammunition and other solder	100,200	6
Fuse alloys	186,800	12
Manufacturing alloys	513,400	32
Other and unspecified alloys [2]	222,000	14
Total consumption	1,592,000	100

[1] Last 11 months only; figures for February through December compiled by National Production Authority, U. S. Department of Commerce.
[2] Principally rectifier coatings.

TABLE 2.—Percentage distribution of bismuth in the United States, 1947–51, by major use group [1]

Use group	1947	1948	1949	1950	1951
Pharmaceuticals	52	49	31	36	36
Metal and alloys [2]	48	51	69	64	64

[1] Computed from figures by Bureau of Mines, 1947–50; National Production Authority, 1951.
[2] Principally fabricating alloys but includes pure metal, ammunition solders, fuse alloys, aluminum alloys, and other minor compositions.

STOCKS

Producers' inventories of refined bismuth metal at the end of 1951 were 41 percent above the end of 1950.

PRICES

The New York price for bismuth metal remained unchanged at $2.25 per pound in ton lots throughout 1951, according to the E & MJ Metal and Mineral Markets. The Metal Bulletin (London) quotation for high-purity metal, per pound, 2 cwt. minimum, on January 5 was 17s., subsequent fluctuations being recorded as follows: June 1, 22s. 6d.; December 28, 28s. Bismuth ore, per pound of contained metal, c. i. f., was quoted on December 28 at 18s. 3d., for 65 percent minimum bismuth content, scaling downward to 7s. for ore containing less than 20 percent bismuth.

FOREIGN TRADE [3]

Imports.—Receipts of refined metal in 1951 were 34 percent less than in 1950. The approximate percentage distribution of receipts, by country of origin, was: Peru 86, Yugoslavia 7, Japan 4, Germany 2, and others 1. There were no transactions in chemical compounds, mixtures and salts of bismuth in 1951.

Exports.—Outgoing shipments of bismuth and alloys decreased 26 percent in 1951. The United Kingdom was again the principal recipient, taking 141,686 pounds; Germany received 2,032 pounds; France received 1,000 pounds.

TABLE 3.—Bismuth imported into and exported from the United States, 1942–46 (average) and 1947–51

[U. S. Department of Commerce]

Year	Imports of bismuth [1]		Exports of metal and alloys	
	Pounds	Value	Pounds	Value
1942–46 (average)	324,331	$322,530	61,960	$70,410
1947	310,561	480,808	240,833	452,147
1948	299,824	464,733	352,027	711,354
1949	541,852	833,940	190,882	356,576
1950	781,670	1,287,098	199,253	387,459
1951	514,020	1,003,285	146,998	376,246

[1] Does not include imports of bismuth contained in bismuth-lead bars from Mexico or imports of bismuth contained in concentrates.

TECHNOLOGY

A brief résumé of the Betts process was published.[4]

Bismuth-bearing slimes are also obtained as a byproduct of the Betts Method of lead refining. The slimes are washed, dried and smelted under oxidizing conditions with Na_2CO_3 and NaOH to yield alkaline slags that carry off the arsenic and antimony as sodium compounds, and the copper as oxide. The residue is crude bismuth, containing mainly silver and lead. This is electrolytically refined at 50 to 60° C. in an acid $BiCl_2$ solution containing rather more than 100 gm. hydrochloric acid per litre, and 3 to 4 gm. of bismuth. A Thum's cell is used, the same in principle as that employed in the refining of silver. The lead from the crude bismuth anode passes into solution as lead chloride which concentrates in the electrolyte. Part of the electrolyte is withdrawn from time to time, and the lead chloride crystallised out.

[3] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Digitized by Google

The use of bismuth subcarbonate in treating gastric and duodenal ulcers was described in an article which reported on a clinical survey of 65 cases and concluded that bismuth in sufficient dosage appears to be a most valuable therapeutic weapon.[5]

The refining of bismuth, including the description of a small refinery, was the subject of a technical report.[6]

A review of bismuth[7] and notes on its properties, occurrence, production methods and application were the subjects of articles.[8] Application of a colorimetric method for determining bismuth in tungsten ores was discussed in another article,[9] and a procedure for the photoelectric spot analysis of bismuth and antimony was also described.[10]

A United States patent issued during 1951 relative to bismuth was: Reimert, L. J., and Fatzinger, E. A., Process Relates to Luminous Pigments Activated by Bismuth or Bismuth and Iron: U. S. Patent 2,544,236, Mar. 6, 1951.

WORLD REVIEW

Canada.—Estimated production of bismuth metal in 1951 was 234,000 pounds compared with 223,000 pounds in 1950.[11]

France.—In 1951 the French concern Mines et Usines de Salsigne mined 192,500 metric tons of ore compared with 187,000 tons in 1950. Among the metals recovered were 510 tons (300 tons in 1950) of copper and 59 tons (22 tons) of bismuth in ingots. Sales included 398 tons (773 tons) of copper and 67 tons (14 tons) of bismuth.[12]

Mexico.—No bismuth metal is produced in Mexico. The commodity obtained there, as an impure bismuth alloy, is a byproduct of smelting and refining some lead-silver ores and concentrates. The bismuth minerals of importance, in addition to native metal, include bismuthinite and what is locally called guanajatite (Bi_2Se_3). The commercially important deposits are those found in El Carmen and the San Bernardo Mines near Zimpan, State of Hidalgo, in the Zapuri and Santa Barbara mines in Chihuahua, and in those near the city of San Luis Potosi.

Bismuth output in Mexico increased from 263 metric tons in 1950 to 338 tons in 1951.

United Kingdom.—Imports of bismuth metal amounted to 557,375 pounds for 1951 compared with 378,879 pounds in 1950.

Exports of bismuth metal excluding alloys amounted to 400,023 pounds for 1951 compared to 428,951 pounds in 1950.[13]

U. S. S. R.—The extent of production in the U. S. S. R. is unknown, but in 1940 operations were started by a new bismuth plant at Adrasinan in Tadzhikistran.[14]

Cadmium

By Robert L. Mentch

GENERAL SUMMARY

CONSUMPTION of cadmium in the United States in 1951 was curtailed enough to enable supplies to meet all military and essential civilian requirements despite a 10-percent decrease in primary production. Apparent consumption declined from 9,545,412 pounds in 1950 to 7,172,588 in 1951, owing largely to restrictions placed on end uses of cadmium by the National Production Authority. The reduction in consumption more than offset the decrease in production; as a result, stocks increased substantially. Net exports of metallic cadmium totaled 516,168 pounds in 1951, a reversal of position from 1950, when there was a net import balance of 277,182 pounds. The market price for commercial sticks remained unchanged at $2.55 a pound throughout the year. The Federal Government continued purchases for the National Stockpile.

TABLE 1.—Salient statistics of the cadmium industry in the United States, 1942–46 (average) and 1947–51, in pounds of contained cadmium

	1942–46 (average)	1947	1948	1949	1950	1951
Production (primary)	7,894,521	8,508,146	7,775,657	8,226,617	[1] 9,190,394	8,311,337
Imports (metal)	42,991	20,292	9,809	157,204	630,109	90,065
Exports (metal)	239,700	303,401	955,701	586,135	352,927	606,233
Consumption, apparent	7,906,282	7,726,753	7,797,105	7,486,274	[1] 9,545,412	7,172,588

[1] Revised figure.

Government Regulations.—On January 1, 1951, the National Production Authority, to insure adequate supplies of cadmium for military uses and essential civilian products for which there is no satisfactory substitute, imposed inventory controls on cadmium and limited the purposes for which cadmium, cadmium-containing items, and cadmium-plated items could be produced. The cadmium conservation order, M–19, was amended on March 16, April 26, and July 30, relaxing restrictions on the use of cadmium to permit its increased use in a wide range of military and civilian products. M–19 was amended because inventories of the metal had been accumulating in the hands of producers in anticipation of a larger volume of defense orders.

DOMESTIC PRODUCTION

Cadmium minerals are very rarely found in commercial quantities, hence no ore is mined solely for the recovery of cadmium. The most common mineral, greenockite (CdS, 77.8 percent cadmium), occurs

Digitized by Google

chiefly as a yellow stain or coating on the zinc sulfide, sphalerite. Cadmium metal is recovered almost entirely from zinc sulfide ores or other sulfide ores, principally lead and copper, containing zinc mineralization. With the exception of the ore bodies at Franklin and Sterling Hill, N. J., nearly all of the major zinc deposits in the United States contain cadmium in varying quantities. Zinc concentrates containing as much as 1 percent cadmium are unusual; in general, the content averages less than 0.5 percent. Zinc concentrates from the Tri-State area average about 0.35 percent cadmium and concentrates from mines in the Western States rarely carry more than 0.2 percent cadmium.

TABLE 2.—Cadmium produced and shipped in the United States, 1942–46 (average) and 1947–51, in pounds of contained cadmium

	1942–46 (average)	1947	1948	1949	1950 [1]	1951
Production:

[1] Revised figures.
[2] Excludes compounds made from metal.
[3] Bureau of mines not at liberty to publish figures separately for secondary cadmium compounds.
[4] Value of metal contained in compounds made directly from flue dust or other cadmium raw materials (except metal).

The entire domestic supply of primary cadmium is recovered concurrently with the treatment of ores of other metals as a byproduct from the flue dusts of zinc blende roasting furnaces and lead blast furnaces, from zinc dust collected in the early stages of distillation in zinc retorts, and from the high-cadmium precipitate obtained in purifying zinc electrolyte at electrolytic zinc plants. A relatively small quantity of secondary metal is recovered from old bearings and other alloys but constitutes no great portion of the total supply. It is estimated that about 45 percent of the primary cadmium metal produced in the United States is of foreign origin, obtained from imported flue dust and imported zinc ores and concentrates. Mexico is the chief source of the foreign cadmium-bearing raw materials, followed by Canada and Peru. Because the geographic origin of the metal produced at United States plants cannot be determined accurately, the entire output is presented as domestic production.

The output of primary metallic cadmium and the production of cadmium contained in primary compounds at domestic plants de-

Digitized by Google

creased 8 and 42 percent, respectively, in 1951. Recovery of cadmium in secondary metal and compounds declined 61 percent.

A list of plants producing cadmium metal in the United States in 1951 follows.

Primary metallic cadmium

Colorado: Denver-American Smelting & Refining Co.
Idaho:
    Bradley-Bunker Hill & Sullivan Mining & Concentrating Co.
    Kellogg-Sullivan Mining Co.
Illinois:
    Depue-New Jersey Zinc Co.
    East St. Louis-American Zinc Co. of Illinois
Missouri: Herculaneum-St. Joseph Lead Co.
Montana: Great Falls-Anaconda Copper Mining Co.
Oklahoma:
    Bartlesville-National Zinc Co., Inc.
    Henryetta-Eagle-Picher Co. (Mining and Smelting Div.)
Pennsylvania:
    Donora-United States Steel Co. (American Steel & Wire Div.)
    Josephtown-St. Joseph Lead Co.
    Palmerton-New Jersey Zinc Co.
Texas: Corpus Christi-American Smelting & Refining Co.
Utah: International-International Smelting & Refining Co.

Secondary metallic cadmium

Arkansas: Jonesboro-Arkansas Metals Co.
Kansas: Coffeyville-Sherwin-Williams Co.
New York: Whitestone, L. I.-Neo-Smelting & Refining Co.

Output of cadmium oxide (cadmium content) increased 5 percent during the year, while the cadmium content of sulfide produced decreased 39 percent. Data for the production of other cadmium compounds are unavailable for 1951.

TABLE 3.—Cadmium oxide and cadmium sulfide produced in the United States, 1946–51, in pounds

Year	Oxide		Sulfide [1]		Year	Oxide		Sulfide [1]	
	Gross weight	Cd content	Gross weight	Cd content		Gross weight	Cd content	Gross weight	Cd content
1946	364,285	317,767	3,637,177	1,225,680	1949	570,993	497,876	2,631,888	999,386

1948	334,859	291,847	3,137,035	1,096,770	1951	606,369	528,645	3,118,413	955,742

[1] Includes cadmium lithopone and cadmium sulfoselenide.

CONSUMPTION AND USES

The apparent consumption of primary cadmium in all forms totaled 7,172,588 pounds in 1951, as computed by deducting net exports of metal from production and adjusting for producers', distributors', and compound manufacturers' stock changes. This figure represented a 25-percent decrease over the quantity apparently consumed in 1950. In 1951, as in the previous 3 years, cadmium metal was purchased by the Federal Government for the National Stockpile. About 95 percent of available cadmium is used in electroplating, bearing alloys,

Digitized by Google

and pigments. The remaining 5 percent goes into solders, miscellaneous alloys, laboratory reagents, and photographic chemicals.

Electroplating.—The principal use of cadmium metal is as a protective coating for iron and steel, and, to a much smaller extent, high-copper alloys and other metals and alloys. Although cadmium may be applied by spraying or hot dipping, it is most commonly electrodeposited. Items commonly electroplated with cadmium include nails, screws, rivets, bolts, nuts, washers, fasteners, springs, electrical contacts, carburetor and magneto parts, and miscellaneous parts for a wide variety of products, including aircraft, ordnance, and automobiles.

Cadmium Bearing Alloys.—The second largest use of cadmium is as a bearing alloy. Cadmium-base bearing metals are used successfully in internal-combustion engines for service under high pressures and temperatures and at high speeds. The bearing alloys are generally of two types—the cadmium-nickel bearing, composed of 98.5 percent or more cadmium and 1.2 percent nickel, and the cadmium-silver bearing, containing 98.3 percent or more cadmium, 0.7 percent silver, and 0.6 percent copper.

Cadmium Solders and Other Cadmium Alloys.—Relatively small quantities of cadmium metal are used in the manufacture of low-melting-point alloys (chiefly tin-lead-cadmium and zinc-lead-cadmium) for soldering and brazing, and fusible alloys, composed largely of lead, bismuth, and cadmium, for sprinkler apparatus, fire-detector systems, and valve seats for high-pressure gas containers.

Cadmium Compounds.—Cadmium sulfide and cadmium sulfoselenide are standard agents for imparting high-quality yellow and red colors, respectively, to paint, soap, rubber, glass, ceramic glazes, paper, textiles, artists' colors, luminescent colors, leather, printing ink, and other products. A table listing the more important cadmium compounds, their physical properties, and uses can be found in the Cadmium chapter of Minerals Yearbook, 1949 (pp. 187–188).

STOCKS

Total domestic stocks of cadmium metal and compounds, exciuding consumers' stocks, for which data are not available, increased 76 percent. Details are given in table 4.

TABLE 4.—Cadmium stocks at end of year, 1950–51, in pounds of contained cadmium [1]

	1950 [2]			1951

PRICES

The quoted New York price of $2.55 a pound for commercial sticks of cadmium, established December 1, 1950, continued in effect throughout 1951. The price for special shapes remained unchanged at $2.80 a pound from December 1, 1950, through December 31, 1951. The average price received by producers of primary cadmium during the year was $2.50 a pound compared with $2.02 a pound in 1950.

The London market quoted cadmium at 18s. 3d. ($2.55) to 18s. 9d. ($2.62) per pound throughout the year.

FOREIGN TRADE [1]

Total imports for consumption of metallic cadmium and of cadmium contained in flue dust decreased 24 percent in weight and 14 percent in value in 1951. The total value of exports, principally metal, increased 175 percent over 1950.

Imports.—Imports of cadmium-bearing flue dust, all obtained from Mexico, were slightly larger than in 1950. Imports of metallic cadmium, however, declined more than 85 percent from the 1950 level. Of the 90,065 pounds imported, Belgium-Luxembourg supplied 59 percent, Japan 20 percent, Australia 11 percent, the Netherlands 6 percent, Canada 4 percent, and Sweden a small quantity.

TABLE 6.—Cadmium exported from the United States, 1949–51, by kinds, in gross weight

[U. S. Department of Commerce]

Kind	1949		1950		1951	
	Pounds	Value	Pounds	Value	Pounds	Value
Dross, flue dust, residues, and scrap	500	$125	----------	----------	200, 579	$10, 029
Metal	566, 135	1, 264, 307	352, 927	$794, 540	606, 233	2, 198, 311
Alloys	3, 000	6, 150	9, 106	11, 575	5, 639	9, 311
Total	----------	1, 270, 582	----------	806, 115	----------	2, 217, 651

exported, the United Kingdom received 49 percent, France 42 percent, Germany 4 percent, Sweden 2 percent, and 12 other countries the remaining 3 percent. Exports of cadmium alloys decreased from 9,106 pounds in 1950 to 5,639 pounds in 1951. Canada received 89 percent of the total and Chile and Germany the remainder.

Tariff.—Action taken at the Geneva Trade Conference of 1947 reduced, as of January 1, 1948, the import duty on cadmium metal from 7½ cents per pound as established in the Canadian Trade Agreement of 1939 to 3¾ cents per pound. Cadmium contained in flue dust remained duty free in 1951.

WORLD PRODUCTION

World production of cadmium in recent years, insofar as data are available, is shown in table 7.

Carbon Black

By D. S. Colby, H. J. Barton, and B. E. Oppegard

GENERAL SUMMARY

PRODUCTION of carbon black in the United States in 1951 totaled 1,677 million pounds, 21 percent above 1950. Total shipments increased 4 percent to 1,563 million pounds. Producers' stocks increased 114 million pounds to 203 million.

Largest gains were made in production and shipments of furnace blacks. Production of furnace blacks increased 35 percent in 1951. Shipments of furnace blacks increased 16 percent, while shipments of contact blacks declined 12 percent. Furnace blacks were 62 percent of total shipments in 1951 compared with 56 percent in 1950.

Stocks of contact blacks rose from a 36-day supply at the first of the year to an 88-day supply on December 31, 1951. Stocks of furnace blacks rose from a 10-day to a 30-day supply.

The value at plants of total production was $107,436,000. The average value was 6.41 cents per pound compared with 6.12 cents in 1950.

"Rest of Texas" showed the largest gain in production, and Arkansas produced carbon black for the first time.

TABLE 1.—Salient statistics of carbon black produced from natural gas and liquid hydrocarbons in the United States, 1947–51

	1947	1948	1949	1950	1951

Average per pound.....cents	5.36	5.88	6.10	6.12	6.41

The quantity of natural gas used in producing carbon black increased slightly to 426 billion cubic feet with an average value of 5.21 cents per thousand cubic feet. Liquid hydrocarbons consumed increased 69 percent in quantity to 182 million gallons and were the source of 52 percent of the furnace blacks produced.

Exports increased 8 percent to 433 million pounds. They were controlled by the United States Department of Commerce during the entire year.

At the end of 1951, 58 plants were producing. Three new furnace plants began operation in 1951. Part of a furnace plant was moved

Digitized by Google

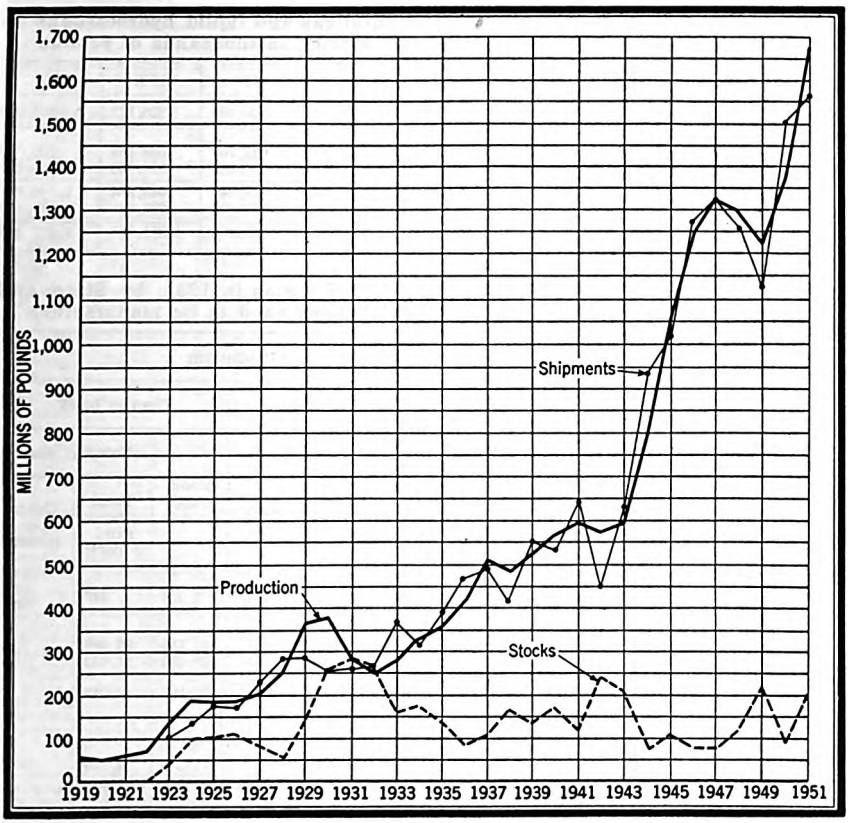

FIGURE 1.—Production, stocks, and shipments of carbon black, 1919–51.

from Kansas to Arkansas, and another furnace plant was moved from Oklahoma to Texas. Daily capacity at the end of 1951 was 5,163,000 pounds compared with 4,075,200 at the end of 1950.

PRODUCTION

By States.—Production increased in all producing States in 1951, and Arkansas produced carbon black for the first time. "Rest of Texas" showed the largest increase in production owing mainly to two new plants.

By Months.—Production of furnace grades rose steadily throughout 1951, averaging close to 2.5 percent gain per month. The production of contact grades held steady through the year, with some tendency to drop in the closing few months.

By Grades.—Production of contact blacks increased 5 percent above 1950, and production of furnace grades in 1951 was 35 percent above 1950. Furnace blacks represented 61 percent of total production in 1951 compared with 55 percent in 1950 and 49 percent in 1949. The production of high-abrasion furnace black exceeded that of any one other furnace grade and also showed the greatest increase in rate of production during the year.

[1] Detail will not add to totals, because some producers operate in more than one area.
[2] Partly estimated.
[3] Comprises 18,820 million cubic feet used by furnace-plant operations in Arkansas, California, Oklahoma, and Kansas and 63,124 million cubic feet used by contact-plant operations in Kansas and New Mexico.
[4] Comprises 1,627 thousand dollars (8.64 cents per M cu. ft.) of natural gas used in Arkansas, California, Oklahoma, and Kansas for manufacture of furnace black and 3,129 thousand dollars (4.96 cents per M cu. ft.) used in Kansas and New Mexico for manufacture of contact black.

[1] Semireinforcing furnace.
[2] High-modulus furnace.
[3] Fast-extrusion furnace.
[4] High-abrasion furnace.
[5] Compiled from reports of the National Gas Products Association and of producing companies not included in the association figures. Figures adjusted to agree with annual reports of individual producers.

Methods and Yields.—The average yield of contact black from natural gas continues to improve slightly each year; it reached 1.79 pounds per thousand cubic feet in 1951 compared with 1.75 in 1950. The yield from furnace plants cannot be accurately determined where both oil and gas are used as feed. The approximate yield from gas in 1951 was 7.49 pounds per thousand cubic feet of natural gas used and 2.96 pounds per gallon of liquid feedstock.

Digitized by Google

Natural gas used at furnace plants in 1951 totaled 66 billion cubic feet compared with 58 billion in 1950. Use of liquid hydrocarbons concurrently increased from 108 to 182 million gallons; these fuels yielded 52 percent of the furnace blacks produced. In 1950 liquid hydrocarbons produced 43 percent of the furnace blacks.

Liquid feed was used at 15 furnace plants in 1951, whereas in 1950 only 7 plants used it.

TABLE 5.—Natural gas and liquid hydrocarbons used in the manufacture of carbon black in the United States, and average yield, 1947–51

Number and Capacity of Plants.—The number of contact-type plants operating in 1951 remained unchanged at 35. The number of furnace plants operating at the end of 1951 was 23, 5 more than at the end of 1950. Three of these plants were entirely new: (1) The Continental Oil Black Co. plant in Calcasieu Parish, La.; (2) the J. M. Huber Corp. plant in Harris County, Tex.; and (3) the United Carbon Co. plant in Wheeler County, Tex. Columbian Carbon Co. moved a unit of its furnace plant in Grant County, Kans. to Union County, Ark. The furnace plant of General Atlas Carbon Co. in Texas County, Okla., which had been idle during 1950, was moved to Howard County, Tex.

The total daily capacity of operating plants at the end of 1951 was 5,163,300 pounds, 1,088,100 pounds over the previous year. The daily capacity of operating contact plants decreased 42,100 pounds to 1,662,100 pounds. The daily capacity of operating furnace plants increased 1,130,200 pounds to 3,501,200 pounds. New and reconstructed plants represented 539,700 pounds of this additional capacity. The remaining 543,400 pounds was capacity added to existing plants.

Producers.—One new producer began operations in 1951, Continental Oil Black Co. One producer, Charles Eneu Johnson Co., Inc., sold its production facilities to United Carbon Co.

which 43 percent was synthetic, whereas, in 1951 it was 1,213 thousand long tons, of which 63 percent was synthetic. Sales of carbon black to rubber companies in 1951 increased 3 percent to 1,061 million pounds. Because of the enlarged percentage of synthetic, average loading of new rubber increased by 45 pounds to 843 pounds per ton, assuming 5 percent loading for reclaim.

Sales of carbon black for ink declined and for paint increased only slightly in 1951. The considerable increases in these categories in 1950 thus appear to have been the result, in part, of scare buying.

TABLE 8.—Sales of carbon black for domestic consumption in the United States, 1947–51, by use, in thousands of pounds

Use	1947	1948	1949	1950	1951

Paint	8,137	6,799	7,005	11,139	11,366
Miscellaneous	16,707	22,634	15,976	16,661	11,554
Total	1,000,684	932,433	822,166	1,109,071	1,129,645

STOCKS

Producers' stocks of both contact and furnace blacks increased gradually during the first half of 1951 and very rapidly during the latter half. By the end of 1951 stocks had approximately recovered the depletion that took place during 1950 and were still increasing. The day's supply of contact types rose from 36 at the beginning of the year to 88 at the end. Furnace-type stocks rose from a 10- to a 30-day supply.

TABLE 9.—Producers' stocks of contact- and furnace-type blacks in the United States, Dec. 31, 1947–51, in thousands of pounds

Year	Furnace						Contact	Total
	SRF [1]	HMF [1]	FEF [1]	HAF [1]	Other	Total		
1947	[2]	[2]	[2]	[2]	[2]	66,493	8,619	75,112
1948	[2]	[2]	[2]	[2]	[2]	90,597	27,646	118,243

[1] For explanation, *see* table 4.
[2] Data not available.
[3] Adjusted figures (reclassification of grade).

PRICES

The average value of both furnace blacks and contact blacks increased above the 1950 figures. Furnace-black average value increased 0.31 cent per pound to 5.57 cents, and contact black increased 0.55 cent to 7.74 cents. Part of this increase can be attributed to the production of a higher proportion of the higher-valued grades, such as HAF (High-Abrasion Furnace). The market values as reported in the Oil, Paint and Drug Reporter remained unchanged throughout 1951.

Digitized by Google

The average value of natural gas used at carbon black plants increased in all States. Arkansas, California, Kansas, and Oklahoma showed values considerably above the average. The manufacture of carbon black in California is secondary to the production of hydrogen, so that gas value does not directly influence carbon-black production there. In Arkansas a large part of the feedstock is liquid hydrocarbons, and only a small amount of gas is used. Kansas and Oklahoma are losing their carbon-black production to areas with lower gas prices and to oil blacks. In 1947 Kansas and Oklahoma each had four operating plants; in 1951 Kansas had three and Oklahoma only one. It seems likely that in Kansas, where the price rise has been more recent, plants will be shut down, moved, or converted to oil.

[1] Chiefly Easy-Processing (EPC) and Medium-Processing (MPC) but also includes Hard-Processing (HPC) and Conductive (CC) channel blacks.
[2] No quotation.

FOREIGN TRADE [1]

Imports.—Imports of "acetylene black" from Canada in 1951 totaled 9,441,895 pounds, with an average value of 13.3 cents per pound. Small quantities, totaling 37 pounds, were received from the United Kingdom and Switzerland. Other carbon-black imports totaled 129,697 pounds—122,900 pounds from Canada, 6,550 pounds from the United Kingdom, and the rest from the Netherlands, Germany, Switzerland, and Japan.

Exports.—The volume of exports in 1951 was limited by quota but was nevertheless 8 percent greater than in 1950. Most notable was the increase in exports to France from 52 million pounds in 1950 to 74 million in 1951. Italy also received considerably larger quantities and exports to Japan returned to a high level after having dropped sharply in 1950. Exports to the United Kingdom declined, but less so than would have been expected, considering their own recently completed producing plants.

[1] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

WORLD PRODUCTION

The more important producers of carbon black, aside from the United States, in 1951 were Germany with a production of approximately 90 million pounds, Japan with a production of about 10 million pounds, and the United Kingdom. The last country was producing at the end of 1951 at the approximate rate of 70 million pounds per year, but actual production during the year is estimated at half this quantity.

Cement

By Oliver S. North and Esther V. Balser

GENERAL SUMMARY

BOTH production and apparent consumption, as indicated by mill shipments, continued their postwar increases throughout 1951. Demand for cement during the year resulted in another record-breaking output, as 249.5 million barrels [1] of hydraulic cement was produced—8 percent more than in 1950, the previous record year. Nevertheless, production of one group of hydraulic cements—natural, masonry (natural), and puzzolan cements—was considerably lower than in 1950. The portland-cement industry operated at 87 percent and the remainder of the hydraulic cement industry at 83 percent of productive capacity during 1951. Mill shipments of portland cement totaled 241.2 million barrels—an increase of 6 percent over the 1950 figure and a new record. Shipments of other hydraulic cements decreased 18 percent. Stocks of all hydraulic cements on hand at mills December 31, 1951, amounted to 18.2 million barrels—36 percent more than at the end of 1950.

The average net mill realization per barrel of portland cement reached $2.54—a 19-cent increase over the average 1950 net realization. Other hydraulic cements, as a group, reported a 31-cent gain per barrel to $2.83.

The long-term trend, as shown by the moving 12-month total of production of finished portland cement in the Bureau of Mines Monthly Cement Reports, continued the upward swing begun immediately after World War II and reached a new alltime high in December 1951.

Monthly production of portland cement during 1951 totaled 17.4 million barrels in January, dropped to 15.2 million barrels in February, and then increased from month to month through October, except for a slight drop in September. A new record—22,797,000 barrels—was set in October. Production figures declined slightly in the last 2 months of the year but remained unusually high. The monthly average for the year was just over 20½ million barrels.

The pattern of monthly shipments from mills in 1951 was similar to that of 1950, but at a higher level, especially in the first 5 months of the year and in October, in which month over 26 million barrels were shipped. Shipments in the last 2 months of 1951 dropped rapidly from the October high and in both November and December were lower than in the corresponding month of 1950.

Through the first 5 months of 1951, except for a slight increase in March, stocks were lower than in 1950, but throughout the rest of the year producers managed to maintain stocks at 2 to 3 million barrels higher than in the same months of 1950. By year end, nearly 5 million more barrels of finished cement was on hand than at

[1] Barrel as used in this chapter, unless otherwise indicated, refers to a 376-pound barrel.

Digitized by Google

the end of 1950, the total being 17,993,000 barrels. Maximum for the year was reached on March 31, whereas the year's low was recorded at the end of October, when 7,162,000 barrels was in stock.

Consumption trends of portland cement in 1951, as indicated in figure 1, continued to be essentially the same as in 1950. The Middle States were again the leading consuming area.

States in the regions shown in figure 1 are as follows: Northeastern—Connecticut, Delaware, District of Columbia, Maine, Maryland, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, and Vermont; Southern—Alabama, Arkansas, Florida, Georgia, Kentucky, Louisiana, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia, and West Virginia; Middle—Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin; Rocky Mountain—Arizona, Colorado, Idaho, Montana, Nevada, New Mexico, Utah, and Wyoming; and Pacific—California, Oregon, and Washington.

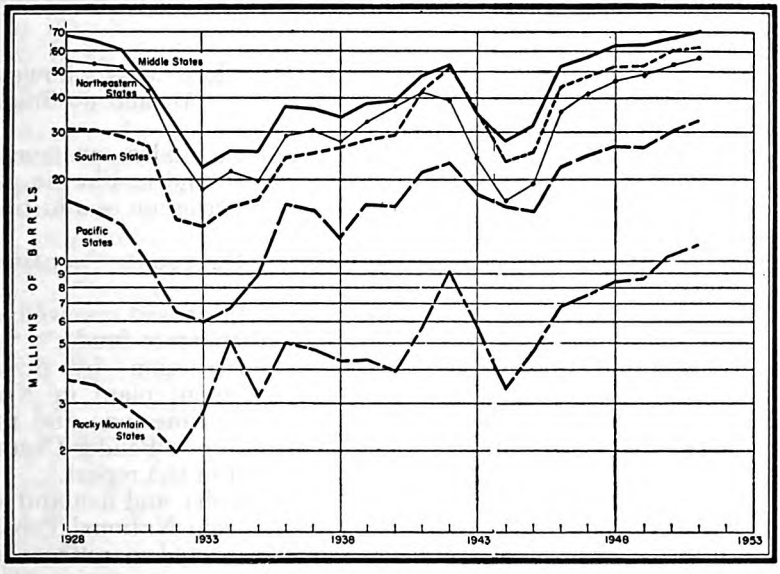

FIGURE 1.—Indicated consumption of portland cement in continental United States, 1928–51, by regions.

Five new cement-manufacturing plants were put in operation in 1951. Production began early in the year at the General Portland Cement Co. wet-process plant at Eagle Ford, Tex. Lone Star Cement Corp. began production in June at its 2-kiln, 4,000-barrel-per-day, dry-process plant near Roanoke, Va. Late in the year Lone Star completed its 1,500,000-barrel-per-year dry-process plant at Maryneal, Tex. In August, Ideal Cement Co. completed conversion to cement manufacture of a wartime alumina plant at Baton Rouge, La. This wet-process plant has a rated capacity of 1,500,000 barrels per year. Late in the year Marquette Cement Manufacturing Co.

[6] Shipments from domestic mills minus net exports.

completed its new wet-process plant at Brandon, Miss.; however, only a small output of clinker was produced in 1951, and no finished cement was produced and shipped.

A new plant near Bunnell, Fla., was reported under construction by Lehigh Portland Cement Co. Increased demand in Florida gave impetus to the project, besides encouraging construction of additional storage facilities in the State.

Many other cement producers throughout the country continued to expand and improve their facilities.

Tightness of cement supply in North Dakota caused renewed discussion of the possibility of erecting a plant with State funds.[2]

A five-man commission recommended construction—by private capital or by the State, if necessary—of a cement plant in North Carolina. A survey of the State disclosed that limestone and marl suitable for manufacturing portland cement occur in Pender County. A 1,000,000-barrel-per-year plant was suggested in the report.[3]

Indicative of the better balance between capacity and demand was the removal of cement on November 7, 1951, from National Production Authority's List A of Notice 1, which restricted manufacturer's inventories of scarce materials. Spot shortages were noticeable in some areas, and in many instances private users were forced to purchase out-of-area cements at higher delivered costs.

PRODUCTION, SHIPMENTS, AND STOCKS

PORTLAND CEMENT

Portland cement, which constituted nearly 99 percent of the hydraulic cements produced in 1951, was manufactured in 155 active plants in 36 States and Puerto Rico. Two new plants began production in Texas in 1951, as did single plants in Virginia and Louisiana.

[2] Rock Products, vol. 54, No. 2, February 1951, p. 79.

The dry-process plant at Devils Slide, Utah, produced a small quantity of finished cement in 1951, after having been idle during 1950.

Output in 1951 was greater than in 1950 in 18 of the 19 districts defined by the Bureau of Mines. The changes from 1950 figures ranged from a 1-percent decrease in Kansas to a 32-percent increase in Puerto Rico. The greatest increase in continental United States was made by the Western Pennsylvania-West Virginia district, where production was up 16 percent. As usual, the Eastern Pennsylvania-Maryland district manufactured the greatest quantity, and output in California was again considerably higher than in the previous year, reaching nearly 30 million barrels in 1951. Eleven districts reported outputs exceeding 10 million barrels.

Shipments in 1951 were higher than in 1950 in all districts except the Kansas and the Western Missouri-Nebraska-Oklahoma-Arkansas districts; the former reported a decline of nearly 7 percent. Gains in continental United States ranged up to 17 percent in the Western Pennsylvania-West Virginia district, whereas shipments from mills in Puerto Rico were 35 percent higher than in 1950.

Stocks of finished cement were 37 percent higher on December 31, 1951, than on the same date of the preceding year. Stocks were higher in all districts except Puerto Rico and Western Pennsylvania-West Virginia, which were 78 percent and 18 percent, respectively, lower. Stocks were more than double the preceding December 31 figure in the Kansas, Western Missouri-Nebraska-Oklahoma-Arkansas, and California districts. The trend of month-end stocks of clinker followed essentially the 1950 pattern through the first 8 months of 1951, although at a lower level. During the last 4 months of the year, stocks of clinker were higher than in 1950 but followed a similar pattern, reaching a low for the year in October and then increasing through December.

Clinker	4,699,461	do	3,544,000	April	8,194,000

[1] Includes Puerto Rico.
[2] Revised figure.

NATURAL, MASONRY (NATURAL), AND PUZZOLAN CEMENTS

Hydraulic cements other than portland were produced in nine plants in 1951. Output, shipments, and stocks during the year were, respectively, 19, 18, and 14 percent lower than in 1950. Producers of this group reported consumption of 44,611 short tons of coal and 175,056,000 cubic feet of gas (equivalent to approximately 3,661 short tons of coal).

TABLE 5.—Natural, masonry (natural), and puzzolan (slag-lime) cements produced, shipped, and in stock at mills in the United States, 1947–51

Year	Production		Shipments		Stocks on Dec. 31, barrels [1]
	Active plants	Barrels [1]	Barrels [1]	Value	
1947	9	2,951,098	2,927,885	$5,764,398	145,408
1948	9	3,440,248	3,375,135	7,734,289	209,901
1949	9	3,185,229	3,233,525	8,006,361	161,605
1950	9	4,246,299	4,218,580	10,629,586	[2] 189,323
1951	9	3,449,463	3,475,423	9,832,956	163,363

[1] Barrel, as used in this chapter, unless otherwise indicated, refers to a 376-pound barrel.
[2] Revised figure.

TYPES OF CEMENT

A breakdown of the total production of portland cement by various types for the 1947–51 period is shown in table 6. The output and shipments of all types except oil-well, white, and miscellaneous cements were higher than in 1950. Marked percentage increases were noted for the low-heat, portland-puzzolan, and air-entrained types.

Prepared Masonry Mortars.—Production of these mixed materials was reported by 100 plants in 1951 and totaled 11,007,893 barrels. Shipments reached 10,829,868 barrels valued at $33,518,197, an average mill value of $3.09 per barrel. These data are not included in the statistical tabulations in this chapter, but the portland cement used in manufacturing these mixtures is included.

CAPACITY OF PLANTS

The total estimated annual capacity of all portland-cement plants in 1951, as reported to the Bureau of Mines by producers, increased 5 percent over that reported in 1950 and reached 281,532,000 barrels.

The overall rate of operations in 1951 was 87 percent of the total capacity, as compared with 84 percent in 1950. As indicated in table 7, the percentage of capacity utilized rose in 15 and decreased in 4 districts. In continental United States the changes ranged from a decrease of 15 percentage points in the Virginia-Georgia-Florida-Louisiana-South Carolina district to an increase of 10 percentage points in the Western Pennsylvania-West Virginia district. The apparent decrease in the Southeastern States is deceptive; actually it is due largely to the fact that new plants and additional facilities at old plants were in full-scale operation and contributing to the years production total for only a minor part of the year, and the capacity utilization figure is computed from all capacity available at year-end.

TABLE 7.—Portland-cement-manufacturing capacity of the United States, December 31, 1950–51, by districts

District	Estimated capacity Dec. 31 (barrels)		Percent of capacity utilized

Oregon, Washington	8,095,216	8,247,825	84.0	**93.0**
Puerto Rico	3,850,000	4,107,220	83.6	**103.2**
Total	268,273,305	281,532,328	84.3	**87.4**

The percentages of capacity utilized in each of the first 7 months of 1951 were higher than during the corresponding months of 1950. After a slight drop in August, a peak figure of 100 percent of capacity was recorded in September. The percentage of capacity utilized was lower for each of the last 3 months of the year than in 1950.

The total capacity of both wet- and dry-process plants continued to increase, as shown in table 9. Wet-process plants made up slightly over 55 percent of the total productive capacity. The percentage of cement produced by wet-process plants in 1951 showed little change from 1950.

[1] Includes Puerto Rico.

A grouping of the cement plants based on their annual capacity is shown below. Total number of plants is 156 instead of the 155 shown in table 6, because this listing includes 1 new plant, which was completed toward the end of the year. Gains of 5 plants and 1 plant, respectively, were made by the 2,000,000–3,000,000-barrel-capacity and the 1,000,000–2,000,000-barrel-capacity groups, whereas the number of large plants in the 3,000,000–10,000,000-barrel-per-year group remained unchanged. In 1951 there were 2 fewer plants in the less-than-1,000,000-barrel-capacity group than in 1950.

Number of portland-cement plants in the United States (including Puerto Rico) in 1951, by size group

Estimated annual capacity, December 31, barrels:	*Number of plants*
Less than 1,000,000	23
1,000,000 to 2,000,000	86
2,000,000 to 3,000,000	34
3,000,000 to 10,000,000	13
Total	156

CLINKER PRODUCTION

The output of clinker, the intermediate product between raw materials and the finished cement, was 10 percent higher in 1951 than in 1950. As in the preceding year, peak production was attained in October, whereas stocks reached their greatest accumulation in April. Stocks of clinker on December 31, 1951, were 20 percent greater than those reported at the end of 1950.

[1] Including Puerto Rico.
[2] Compiled from monthly estimates of producers.
[3] Revised figures.
[4] Preliminary figures.

RAW MATERIALS

Among the raw materials used for manufacturing cement, the "limestone and clay or shale" classification represented 69 percent of the total output in 1951—a decline of 4 percentage points as compared to 1950. "Cement rock and pure limestone" were the raw materials used in manufacturing 20 percent of the total—1 percentage point less than in 1950. The percentage made from "blast-furnace slag and limestone" nearly doubled the 1950 figure and amounted to 10 percent of the output. The percentage of cement produced from "marl and clay" remained the same as in 1950 and represented 1 percent of the total output.

TABLE 12.—Production and percentage of total output of portland cement in the United States,[1] 1946–51, by raw material used

	Cement rock and pure limestone		Limestone and clay or shale [2]		Marl and clay		Blast-furnace slag and limestone	
	Barrels	Percent	Barrels	Percent	Barrels	Percent	Barrels	Percent
1946	39,070,643	23.8	112,142,154	68.3	2,720,500	1.7	10,130,891	6.2
1947	43,428,201	23.3	129,338,247	69.3	2,408,845	1.3	11,344,054	6.1
1948	47,559,783	23.1	144,855,487	70.5	2,620,060	1.3	10,412,933	5.1
1949	45,655,516	21.8	150,435,948	71.7	3,310,270	1.6	10,325,683	4.9
1950	47,120,142	20.8	164,811,547	73.0	2,596,962	1.1	11,497,198	5.1
1951	50,328,000	20.4	169,204,269	68.8	2,653,211	1.1	23,836,996	9.7

[1] Includes Puerto Rico, 1946–51; Hawaii, 1946. There has been no production in Hawaii since 1946.
[2] Includes output of 5 plants using oystershells and clay in 1946–49; 6 plants in 1950; and 7 plants in 1951.

The tonnages of raw materials (exclusive of fuels and explosives) required to produce portland cement in recent years are given in table 13. Limestone (including oystershells), cement rock, and clay and shale constitute 94 percent of the total materials consumed in 1951. Except for marl, which declined 2 percent, all types of raw materials consumed in 1951 showed gains over the quantities used in 1950. The quantity of limestone and oystershells used again increased over 4 million tons.

Miscellaneous [4]	140,999	148,290	173,902
Total	68,620,985	73,755,919	80,385,328
	Pounds	*Pounds*	*Pounds*
Average total weight required per barrel of finished cement	654	653	653

[1] Including Puerto Rico.
[2] Includes bentonite, diatomaceous shale, and fuller's earth.
[3] Includes iron ore, pyrite cinders and ore, and mill scale.
[4] Includes diatomite, fluorspar, pumicite, flue dust, pitch, red mud and rock, hydrated lime, tufa, cinders, calcium chloride, sludge, grinding aids, and air-entraining compounds.

FUEL AND POWER

All of the types of fuel consumed in the portland-cement industry were used in greater quantity in 1951 than in 1950. The percentage gains for the various fuels were as follows: Coal, 7 percent; fuel oil, 21 percent; natural gas, 6 percent; and byproduct gas, 30 percent.

The number of plants using electric energy, the kilowatt-hours generated and purchased, and the average electric energy used per barrel of cement are shown in table 16. Although cement plants generated more electric energy than in 1950, the percentage generated at plants was 2 percent less of the overall total used than in the previous year. The quantity of electric energy used per barrel of cement produced declined slightly to 22.0 kilowatt-hours.

TABLE 14.—Finished portland cement produced and fuel consumed by the portland-cement industry in the United States,[1] 1950–51, by processes

Process	Finished cement produced			Fuel consumed [2]		
	Plants	Barrels	Percent of total	Coal (short tons)	Oil (barrels of 42 gallons)	Natural gas (M cubic feet)
1950						
Wet	89	127,315,811	56.3	3,735,896	4,074,038	67,384,771
Dry	61	98,710,038	43.7	4,207,267	1,187,190	[3] 29,779,788

EMPLOYMENT AND PRODUCTIVITY

Trends in employment and output per man in the cement industry over the period 1944–48 are shown in tables 17 through 19; table 20 gives a breakdown of output per man-hour on the basis of hours of labor per day for 1946–48, and tables 21 through 23 show breakdowns of employment figures on a producing district basis for 1947 and 1948.

TABLE 17.—Employment in the portland-cement industry, finished cement produced, and average output per man in the United States,[1] 1944–48

Year	Employment					Production			Percent of industry represented[2]
	Average number of men	Time employed		Man-hours		Finished portland cement (barrels)	Average per man (barrels)		
		Average number of days	Total man-shifts	Average per man per day	Total		Per shift	Per hour	
1944	20,376	278	5,670,147	8.0	45,236,906	89,883,262	15.85	1.99	[3] 100.0
1945	20,695	287	5,937,680	8.0	47,612,919	101,340,500	17.07	2.13	[3] 100.0
1946	25,044	313	7,836,818	8.0	62,384,279	162,296,274	20.71	2.60	[3] 100.0
1947	26,962	318	8,569,626	7.9	67,936,375	184,644,179	21.55	2.72	[3] 100.0
1948	27,648	329	9,088,519	8.0	72,291,915	203,007,875	22.34	2.81	100.0

[1] Exclusive of Puerto Rico and Hawaii. There has been no production in Hawaii since 1946.
[2] Calculated for each year by dividing quantity of finished cement produced at mills included in the employment survey by total production as determined by the production survey.
[3] Revised figure.

TABLE 18.—Mill employees in the portland-cement industry, finished cement produced, and average output per man in the United States,[1] 1944–48

Year	Employment—cement mills only					Production			Percent of industry represented
	Average number of men	Time employed		Man-hours		Finished portland cement (barrels)	Average per man (barrels)		
		Average number of days	Total man-shifts	Average per man per day	Total		Per shift	Per hour	
1944	15,566	289	4,501,364	8.0	35,826,375	89,883,262	19.97	2.51	[2] 100.0
1945	16,142	299	4,820,735	8.0	38,551,413	101,340,500	21.02	2.63	[2] 100.0
1946	18,101	325	5,874,801	7.9	46,610,334	162,296,274	27.63	3.48	[2] 100.0
1947	18,327	330	6,056,358	7.9	47,716,276	184,644,179	30.49	3.87	[2] 100.0

TRANSPORTATION

The quantity and proportion of cement shipped by each of the major methods of transportation for 1948–51 are listed in table 24. Owing to several revisions in the 1948 and 1949 figures it was considered advisable to include those years in the present table. The percentage shipped in bulk increased 6 percentage points from 1950 to 1951 to 61 percent of the total shipments. A 3-percentage-point increase in the proportion of shipments by truck was noted, whereas the proportion shipped by rail decreased 2 percentage points and the proportion shipped by boat decreased slightly.

TABLE 24.—Shipments of portland cement from mills in the United States,[1] 1948–51, in bulk and in containers, by type of carrier

[1] Includes Puerto Rico.
[2] Includes steel drums and iron and wood barrels.
[3] Revised figure.
[4] Includes cement used at mills by producers as follows—1948: 645,420 barrels; 1949: 643,174 barrels; 1950: 929,451 barrels; 1951: 1,368,117 barrels.
[5] Less than 0.05 percent.

CONSUMPTION

Table 25 shows that the indicated consumption of portland cement in 1951 was higher in 29 States and lower in 19 States and the District of Columbia compared to 1950. Percentage increases ranged up to 29 percent in Maine and Oregon, with Ohio, Florida, Nevada, Colorado, Louisiana, and Virginia also showing substantial gains. Largest percentage decline was in South Dakota, where apparent consumption

Digitized by Google

was 25 percent lower than in 1950. California, Texas, New York, Pennsylvania, Ohio, Illinois, and Michigan, in that order, were the largest consumers of cement in 1951. These 7 States accounted for 47 percent of the total consumption in continental United States, and the 12 non-cement-producing States and the District of Columbia accounted for 12 percent.

TABLE 25.—Destination of shipments of finished portland cement from mills in the United States, 1949–51, by States

LOCAL SUPPLY

The surplus or deficiency in the quantity of cement locally available is indicated in table 27. The comparison is based on shipments from mills and on consumption shown by State receipts of mill shipments. The 1951 deficiencies occurred in 2 States and in all 6 divisions.

The total surplus from producing States in 1951 was distributed as follows: 28,479,713 barrels to non-cement-producing States, Alaska, and Hawaii; 2,727,647 barrels to destinations outside continental United States (excluding local consumption of Puerto Rican production); and 7,536 barrels to unspecified destinations.

PRICES

The average net mill realization of all portland cement shipped from mills in 1951 advanced to $2.54 per barrel from $2.35 in 1950. The average net mill realization in each quarter of 1951 was: First, $2.53; second, $2.53; third, $2.54; and fourth, $2.55.

The composite wholesale price index (1926=100) of portland cement, f. o. b. plant, according to the Bureau of Labor Statistics, was 147.2 in 1951, whereas in 1950 it was 136.6.

Average mill value per barrel, in bulk, of portland cement in the United States,[1] 1946–51

1946	$1.72	1949	$2.30
1947	1.90	1950	2.35
1948	2.18	1951	2.54

[1] Includes Puerto Rico and Hawaii, 1946; Puerto Rico only, 1947–51. There has been no production in Hawaii since 1946.

FOREIGN TRADE [4]

Imports.—Imports of hydraulic cement amounted to 893,000 barrels in 1951, 37 percent less than in 1950. For the most part, purchases were made from Germany and the United Kingdom (England). Imports of all hydraulic cement, except white, nonstaining, and other special cements, for 1949–51 are listed by country of origin in table 29. Imports of white, nonstaining cement in 1951 amounted to 10,480 barrels valued at $54,270.

TABLE 28.—Hydraulic cement imported for consumption in the United States, 1946–51

[1] Excludes "white, nonstaining, and other special cements."
[2] Revised figure.

Exports.—For the first time in several years cement exports increased over the previous year. Total exports were 2,933,000 barrels valued at $9,964,000. Shipments to South America dropped sharply, but a revived demand from Canada, Mexico, Cuba, and other countries of North America resulted in export to this continent of about 1 million barrels more in 1951 than in 1950.

Shipments of hydraulic cement to possessions and other areas administered by the United States in 1949–51 are shown in table 32.

[4] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

TECHNOLOGY

The Administrative Committee on Standards of the American Society for Testing Materials approved the following revised tentative specifications and methods, which had been recommended by Committee C–1 on Cement: (1) Methods of Chemical Analysis of Portland Cement (C 114–47); (2) Tentative Methods of Chemical Analysis of Portland Cement (C 114–48 T); (3) Tentative Specifications for Air-Entraining Additions for Use in the Manufacture of Air-Entraining Portland Cement (C 226–50 T); (4) Specifications for Portland Cement (C 150–49) and of Tentative Specifications for Air-Entraining Portland Cement (C 175–50 T); (5) Method of Test for Autoclave Expan-

Digitized by Google

sion of Portland Cement (C 151–49); and, (6) Tentative Definition of the Term Addition as Applied to Hydraulic Cement (C 219–48 T).

A technique for measuring with a porosimeter the degree of cement clinker burning was described. The authors believed that the method would be more satisfactory than the former practice of judging degree of burning by appearance, "feel," or measuring liter weight. The porosimeter method was said to be accurate and rapid, requiring less than 5 minutes per determination.[5]

A series of three articles translated from a French publication covered a detailed study of the thermal efficiency of the rotary cement kiln. Obtaining highest possible thermal efficiency in the manufacture of cement is of major concern to the producer because of resultant lower output unit cost. The author found that efficiency of cement kilns varied from 17 to 53 percent.[6]

Another series of articles dealing with all phases of the evaluation and development of maximum cement and lime kiln efficiencies appeared in a trade magazine.[7]

Published in a trade magazine were brief summaries of several reports on cement research in Japan. They dealt with such problems as determinations of fineness, free magnesia and sulfur trioxide, influence of grinding mediums, blast-furnace slag additions, puzzolans, and chemical reactions of cement and aggregates.[8]

Methods of testing for thickening time and rate of hardening, and stability of high-temperature oil-well cement in Mexico were described in an article.[9]

Other papers published included a description of an apparatus and method for quick determination of plasticity of masonry cement mortar [10] and a summary and analysis of research on the influence of cement particle size on strength of concrete.[11]

WORLD REVIEW

Available statistics on world production of cement in 1947–51 are shown in table 33.

Chromium

By Norwood B. Melcher and John Hozik[1]

GENERAL SUMMARY

DOMESTIC production of chromite in 1951 was the highest since the end of World War II, imports were second only to those of 1948, and consumption by each of the three major industries—metallurgical, refractory, and chemical—was the largest on record. World production, with Turkey in the forefront, reached a new peak of 2.8 million metric tons.

Although the new supply of chromite available in 1951 was 10 percent higher than in 1950, the greater rise of 24 percent in domestic consumption caused the balance between new supply and actual consumption to be the closest since 1946. As a result, National Stockpile requirements were not satisfied. Consumers' stocks increased slightly in total but decreased in terms of months' supply.

To enlarge the supply of chromium ores, a depot was established at Grants Pass, Oreg., for purchasing up to 200,000 long tons of specification-grade domestic chromium ores at incentive prices. The program got under way in August and was responsible for the rise in annual output from 400 short tons in 1950 to over 7,000 tons in 1951; the number of operators increased from 1 to 34. At year end, negotiations were in progress between the Government and a private company to reactivate the Mouat mines in Montana.

Government regulations during 1951 included placing chromite and chromium alloys under export-license control. In August the Office of Price Stabilization exempted chromite from the General Ceiling Price Regulation, and the National Production Authority restricted the inventories of chromium ferroalloys to a 45-day supply and required users to submit proposed monthly melt schedules for approval.

Quoted prices for foreign chromite at Atlantic coast ports advanced 18 to 26 percent during the year.

DOMESTIC PRODUCTION

Although chromite was reported produced in the United States as early as 1827, the total output through 1951 (856,000 short tons) would be equivalent to less than 9 months' supply at the 1951 rate of consumption. For the most part, domestic deposits are small, high-cost operations, and the ores generally have a high iron-chromium ratio. As revealed in table 3, only during periods of national emergency is much consideration given to domestic deposits; at all other times United States users rely on the less expensive and more plentiful ores of Southern Rhodesia, Union of South Africa, Turkey, Philippines, New Caledonia, and Cuba.

Production of chromite was confined to one mine during 1950 and the first half of 1951, but opening of the purchase depot at Grants Pass, Oreg., on August 3, 1951, presented a real incentive to miners in Oregon and northern California. R. F. Helmke, operating the Lambert mine in California, shipped 1,975 short tons of 40–42 percent Cr_2O_3 during 1951 and was the only producer active in both years. By the end of 1951 chromite shipments had been recorded from 34 operations.

California.—Of the 14 shippers of chromite from California mines in 1951, the following 5 were the largest in both the State and the United States: Eugene R. Brown, operating the High Plateau mine in Del Norte County; R. F. Helmke (Lambert mine, Magalia, Butte County); Ruth Robertson (Cyclone Gap mine, Preston Peak mining district, Siskiyou County); J. & W. Mining Co. (mine of same name, Gasquet, Del Norte County); and Holliday Mines (mine of same name, High Dome, Del Norte County). Several smaller producers were active in Del Norte County as well as in Siskiyou, Fresno, and Shasta Counties. California mines supplied 89 percent of the United States production in 1951.

In 1951 the Bureau of Mines issued a report on several chromite deposits in San Luis Obispo County, Calif.[2] Reports containing historic descriptive data of individual mines and propects, based on published and unpublished information gathered during World Wars I and II by the United States Geological Survey, have been published in recent years by the California Division of Mines.[3]

Montana.—No chromite was mined in Montana in 1951 or in the 6 previous years. However, negotiations were under way between the American Chrome Corp. and the Federal Government (acting through the Defense Materials Procurement Agency) to reactivate the Mouat

Digitized by Google

mines in Stillwater County. Three-fourths of the domestic chromite reserves are located in this area.

Oregon.—Of the 34 mines that made commercial shipments of chromite during 1951, 20 were in Oregon, principally in Josephine County—the site of Grants Pass Depot. Production was also reported from Curry, Jackson, and Grant Counties. Oregon mines supplied 11 percent of the domestic output.

GOVERNMENT ASSISTANCE

Chromite, with other minerals, benefited from the various types of assistance under the Defense Production Act administered by the Defense Minerals Administration, in the United States Department of the Interior, and its successor agencies established by Executive order on August 28, 1951—the Defense Minerals Exploration Administration, in the Interior Department, and the Defense Materials Procurement Agency. The DMEA had the particular function of stimulating exploration by grants-in-aid to mining companies; depending upon the essentiality of the particular mineral to the defense effort, these grants ranged from 50 to 90 percent of the cost of exploration projects, repayable from sales of the mineral if a project were certified as successful. The percentage fixed for chromite was 50. Although over 1,100 requests were received for Government aid during the year, only 5 applications pertained to chromite; 4 of these were withdrawn or denied, and 1 was still in process at the year end.

The Emergency Procurement Service of the General Services Administration announced in August 1951 opening of a depot at Grants Pass, Oreg., to which producers could ship chrome ores and concen-

Digitized by Google

trates for inspection and purchase by the Government. The program calls for purchasing 200,000 long tons of specification chromium ores and concentrates of domestic origin. Five tons of ore is the minimum shipment accepted, and no more than 2,000 tons a year may be accepted from any one source without prior written approval of the Government. Prices paid are based on the chromic oxide content of the ore and the chromium-iron ratio. The program will terminate either on June 30, 1955 or (1) on December 31, 1954, provided that 1 year's public notice is given in advance of that date or (2) when 200,000 tons of material is received and accepted. The following is abstracted from the GSA announcement:

Chemical Requirements.—No material will be accepted by the Government which does not meet the following specifications: Chromic oxide (Cr_2O_3) content, minimum 42 percent; silica (SiO_2), maximum 10 percent; and chrome-iron ratio, minimum 2 : 1.

Physical Requirements.—Lumpy ore shall be hard, dense, nonfriable material of which not more than 25 percent shall pass a 1-inch Tyler Standard screen. All lump material shall pass through a 12-inch ring. No size restrictions apply to fines or concentrates.

Prices.—The base price for domestic chromite, 48 percent chromic oxide, 3:1 chrome-iron ratio, delivered to the depot is $115 per long dry ton for lumpy material and $110 a ton for fines and concentrates. *Premiums* are paid for analyses exceeding base specifications at the following rates: $4 a ton for each 1 percent of Cr_2O_3 content above 48 percent, plus $4 a ton for each one-tenth increase in Cr-Fe ratio to but not exceeding 3.5 : 1. *Penalties* are assessed for material not meeting base specifications, as follows: $3 a ton for each 1 percent of chromic oxide below 48 percent down to and including 42 percent and $3 a ton for each one-tenth decrease in Cr-Fe ratio down to and including 2 : 1.

The effective prices resulting from the above premiums and penalties are shown in table 8.

CONSUMPTION AND USES

In 1951, for the first time, total chromite consumption exceeded 1,000,000 short tons, and new heights were reached by each of the 3 major chromite-consuming industries. Of the 1,212,480 tons used in 1951 (1950 percentages shown in parentheses), 47 percent (50) was consumed for metallurigcal purposes, 37 percent (36) for refractories, and 16 percent (14) for chemicals. The proportionately larger consumption of refractory and chemical ores reflects the increase in steel-furnace capacity and production, and greater demand for chrome plating, chromium metal, and leather-tanning chemicals. Consumption was remarkably steady at a high level throughout the year, each quarterly total being within the 300,000- to 305,000-ton range. The average chromic oxide content of all grades combined increased from 42.4 percent in 1950 to 42.6 percent in 1951.

Chromite used for metallurgical purposes (in the manufacture of ferrochromium, stainless steel, etc.) increased 17 percent over 1950 and exceeded the World War II record by 3 percent. Ore for refractory uses (in the manufacture of chromium brick, refractory cement, etc.) exceeded the 1950 record by 25 percent. The chemicals industry used 31 percent more chromite than in the previous peak year 1948. The bulk of chromite consumption in the United States is in

Digitized by Google

six adjoining States—New York, Pennsylvania, New Jersey, Maryland, West Virginia, and Ohio.

TABLE 4.—Consumption of chromite and tenor of ore used by primary consumer groups in the United States, 1942–51, in short tons

Year	Metallurgical		Refractory		Chemical		Total	
	Gross weight (short tons)	Average percent Cr_2O_3	Gross weight (short tons)	Average percent Cr_2O_3	Gross weight (short tons)	Average percent Cr_2O_3	Gross weight (short tons)	Average percent Cr_2O_3
1942	479,615	48.5	294,092	34.0	118,245	44.8	891,952	43.2

1950	491,685	47.8	353,642	34.0	135,042	44.6	980,369	42.4
1951	573,075	48.1	440,771	34.7	198,634	44.3	1,212,480	42.6

Consumption of ferrochromium in the United States in 1951 was one-third larger than in 1950 and totaled 195,307 short tons. Additional tonnages of chromium were consumed in the form of chromium metal, briquets, Chrom-X, low-carbon ferrochrome silicon, and miscellaneous chromium alloys. The principal centers of consumption are located in five States—New York, Pennsylvania, Maryland, Ohio, and Michigan. It is estimated that, on a gross-weight basis, 60 percent of the chromium alloys and metal was consumed in making stainless steels (steels containing over 10 percent chrome), about 35 percent in other alloy steels, including high-speed, and the remaining 5 percent in high-temperature alloys and other uses.

National Production Authority Order M–80, issued August 15, 1951, restricted inventories of chromium alloys to a 45-day supply and required all melters and processors to file proposed melting or processing schedules monthly.

An article published in 1950 describes the various stages in the development of ferrochromium.[4] It explains the chemical composition of the three major classes of chromite and gives typical analyses of metallurgical-grade chromium ores from Southern Rhodesia, Turkey, New Caledonia, Russia, and Montana (as well as analyses of refractory ore from the Philippines and chemical ore from the Union of South Africa). It also describes the blending, smelting, and reduction of ores in the manufacture of ferrochromium, the composition and properties of the alloy produced, and the application of the high-carbon ferrochromium in the manufacture of cast iron and steel.

A summary of General Services Administration chromite purchase specifications, by grades, is given in table 5.

(For a detailed discussion of specifications and uses, see Minerals Yearbook, 1950, pp. 239, 240.)

Chemical: [4]							
Friable ore	44	----	----	----	5	----	----

[1] Specification P–11, June 13, 1951, covers chromite ore suitable for the manufacture of commercial ferrochromium and special chromium alloys. Lumpy ore shall be hard, dense, nonfriable material, of which not more than 25 percent shall pass a 1-inch Tyler Standard screen. Material of friable nature, regardless of an initially lumpy appearance, will be classified as fines. No size restrictions apply to fines or concentrates.

[2] Guaranteed analyses superior to that stated are desired, and no offers will be considered unless the chemical analyses are at least within the stated limits in all respects. The right is reserved to reject any proposal for which the proposed guaranteed analysis is inferior to that shown for high grade chromite.

[3] Specification P–12, October 31, 1950, covers refractory-grade chromium ore that is suitable for the production of all chromium-type refractories. Restricted to Philippine Islands and Cuba, although material from other sources will be considered. Material shall consist of "lump ore," of which not more than 20 percent shall pass a Tyler Standard 10-mesh screen.

[4] Specification P–65, June 1, 1949, covers chromium ore intended for the manufacture of chromium chemicals.

STOCKS

Consumers' stocks of all grades of chromite were 5 percent higher at the end of 1951 than in 1950. However, based on the annual rates of consumption in 1951 and 1950, respectively, the 1951 year-end inventories were equivalent to only a 6.3-month supply compared with 7.4 months in 1950.

TABLE 6.—Stocks of chromite at consumers' plants, December 31, 1946–51, in short tons

Grade	1946	1947	1948	1949	1950	1951
Metallurgical	157,281	191,104	256,770	325,881	248,872	305,134
Refractory	92,585	144,381	236,724	303,110	251,663	247,673
Chemical	77,116	75,582	108,997	128,004	105,736	84,646
Total	326,982	411,067	602,491	756,995	606,271	637,453

PRICES

Prices of foreign chromite moved upward during 1951 and on December 31 were 18 to 26 percent higher than at the beginning of the year, according to E&MJ Metal and Mineral Markets. Effective August 10, 1951, the Office of Price Stabilization exempted chromium ores and concentrates from price controls, because domestic buyers had little control over foreign prices.

Although the prices listed in table 7 are fairly representative for metallurgical- and chemical-grade chromite, apparently no quotations are included for refractory material, which represents about one-third

Digitized by Google

of the United States consumption. In 1951, 72 percent of the United States supply of refractory ore originated in the Philippines, 19 percent in Cuba, and the remaining 9 percent in the Union of South Africa and Southern Rhodesia.

Incentive prices paid to domestic producers shipping metallurgical-grade chromite to the Government depot at Grants Pass, Oreg., are listed in table 8. The 1951 base price of $115 a long ton for 48 percent Cr_2O_3 domestic ore with a 3:1 chrome-iron ratio compares with $52.80 paid by the Office of Metals Reserve for like specifications in 1944–45. Premiums paid and penalties assessed for material in variance with the base specifications were considerably lower in World War II than in 1951.

TABLE 7.—Price quotations for various grades of foreign chromite in 1951

[Engineering and Mining Journal]

[1] Prices for the various grades were calculated by Bureau of Mines on basis of the base price, premiums, and penalties prescribed by the Emergency Procurement Service of the General Services Administration. Prices shown are for lump ore; payments for fines and concentrates are $5 a ton lower. Fractions appearing on analysis reports are prorated in computing premiums and penalties.

According to Steel Magazine, quotations on chromium alloys and metal, bulk, carlots, remained steady during 1951—21.75 cents per pound of contained chromium in the form of high-carbon ferrochromium; 33.60 cents a pound of contained chromium for 0.03-percent

Digitized by Google

carbon grade down to 28.75 cents a pound for 2-percent low-carbon ferrochromium; and $1.08 a pound for chromium metal (97 percent Cr min., 1 percent Fe, 0.50 percent C max.). Basic chrome-brick prices were unchanged at $73–$78 per short ton for burned chrome brick and $77–$82 for chemical-bonded chrome brick, f. o. b. Baltimore, Md., or Chester, Pa.

FOREIGN TRADE [5]

The rapid rise in chromite requirements is indicated by the fact that less than 7 million tons of chromite were imported into the United States from 1900 through 1940, but over 12 million tons during the next 11 years; domestic production from 1900–51 totaled less than 600,000 tons.

Imports.—Chromite imports exceeded 1.4 million short tons in 1951, second only to the 1.5 million tons received in 1948. For the first time in 10 years, none was received from U. S. S. R., compared with nearly 400,000 tons supplied by Russia in 1948. The Union of South Africa provided the largest tonnage (25 percent of the total), followed by Turkey with 23 percent, Philippines 22 percent, Southern Rhodesia 16 percent, Cuba 6 percent, and New Caledonia 5 percent. The remaining 3 percent came from India, Sierra Leone, and Yugoslavia. The 1951 tonnages were valued at foreign ports at $25,505,809, an average of $17.85 a short ton, about the same as in 1950. However, in 1951 each of the three classes of ore averaged 1 percentage point lower in chromic oxide content than in 1950.

Chromite is generally classified into three grades as metallurgical, refractory, and chemical, corresponding to the chemical analysis of the ore and its intended use. An examination of the Bureau of Census import statistics as reported in table 9, as well as of the Bureau of Mines survey of actual users, reveals that, whereas metallurgical ore is received from many countries (principally Turkey, Southern Rhodesia, and New Caledonia), refractory ore is supplied by only 4 (Philippines, Cuba, Union of South Africa, and Southern Rhodesia), and chemical-grade by only 1 (Union of South Africa). Although most of the chemical ore shown in table 9 was imported for use by the chromium-chemicals industry and to meet National Stockpile requirements, a certain tonnage is used for metallurgical purposes (as in the manufacture of ferrochromium) by blending with lump ores having a high chromium-iron ratio, and some chemical-grade ore is used in refractory mixes. A small tonnage of refractory ore is also used for metallurgical purposes.

Ferrochromium imports in 1951 increased 18 percent to 27,291 short tons, containing 16,432 tons of Cr valued at $6,123,086. Canada supplied 22,711 tons, or 83 percent of the total.

Tariff.—Chromium ores enter the United States tariff free, but the duty on high-carbon ferrochromium is ⅝ cent per pound of contained chromium. The duty on low-carbon ferrochrome and ferrochrome silicon is 12½ percent ad valorem.

[5] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Exports.—Shipments of chromium ores to foreign destinations totaled 2,030 short tons in 1951 (mostly to Canada), valued at $144,248, compared with 2,044 tons ($63,409) in 1950. Chromite exports reached a peak of 26,259 tons in 1943, but dropped to 1,019 tons in 1944.

Exports of ferrochromium totaled 240 short tons ($96,635), compared with 347 tons in 1950. The 1951 tonnage went to Canada and 12 other countries. Chromic acid exports amounted to 1,007,201 pounds ($301,823).

In April 1951 exports of chromite, chromium alloys, and metal were made subject to United States export-licensing control.

TECHNOLOGY

A description of the use of Chrom-X as a ladle addition in the manufacture of alloy steels was published.[6] The exothermic ferrochromium utilizes low-grade chromium ores and permits closer control of chromium content without chilling the steel bath. Chrom-X is a mixture of ferrochrome, carbon, and silicon and an oxidizing agent, sodium nitrate ($NaNO_3$), so compounded that it reacts exothermically when added to molten iron or steel. The reaction is rapid, with high recovery of chromium and a saving in fuel.

Five tons of ferrochromium prepared from low-grade domestic ores by smelting concentrates in the Bureau of Mines' Electrometallurgical Laboratory, Boulder City, Nev., was shipped in 1951 to the Massillon, Ohio, plant of Republic Steel Corp. for testing as provided for under cooperative agreement. Included was a 3-ton batch of ferrochromium made from typical mill concentrates obtained from the Mouat (Montana) stockpile and 2 tons from Oregon beach-sand concentrates. The ferrochrome produced by the Bureau averaged about 55 percent Cr compared with 68–70 percent for the standard commercial product. The object of the study by Republic was to summarize information covering the characteristics and use of the special ferrochromium in the production of commercial alloy steels. The Bureau of Mines ferrochrome was used in six 100-ton heats of open-hearth alloy steel. An abstract from a report on these tests dated December 22, 1951, and submitted to the Bureau by D. H. Ruhnke, chief metallurgist, Central Alloy district, Republic Steel Corp., follows:

> The average percentage of chromium recovery for the six heats was 84.9 percent, and compares favorably with recoveries obtained from high-carbon ferrochrome supplied by commercial producers. Nonmetallic inclusion testing and etch tests on billet products revealed acceptable material from all of the heats. These tests all compare favorably with tests performed on heats using commercial high-carbon ferrochrome.
>
> The only significant difference noted between the special ferrochrome and commercial ferrochrome was the increased amount of special ferrochrome needed to raise the chromium content of a heat. This was expected because the special alloy has a lower chrome content. The special ferrochrome differs somewhat in appearance from commercial alloy and is much more difficult to fracture. These unimportant differences are attributed to the relatively small batches in which the special ferrochrome was smelted and cast, rather than the difference in chemical composition.

Digitized by Google

The Carboloy department of General Electric Co. announced its series 600 chrome carbides at the World Metallurgical Congress and Metals Exposition in Detroit on October 15.[7] The new carbide series is said to contain about 70 percent chromium by weight and has a nickel binder, but no tungsten or cobalt. Outstanding properties include excellent resistance to abrasion, erosion, and corrosion, lighter weight, and resistance to oxidation at high temperatures. The coefficient of thermal expansion approximates that of steel. Resistance to sulfuric acid is reported to be 30 times that of 18–8 stainless steel and 3 times that of conventional carbides.

WORLD REVIEW

World output of chromite reached an unprecedented total of 2.8 million tons, one-half million tons greater than the previous high of 1950. One of the significant developments of the year was the emergence of Turkey as the world's largest producer. Before 1948 Turkey's greatest effort was 213,600 metric tons produced in 1938; in 1948 production rose to 286,000 tons; in 1949–50 over 420,000 tons was produced each year; and in 1951 Turkish mines produced 602,000 tons.

Afghanistan.—The rich Logar Valley is estimated to contain 50,000 to 100,000 tons of high-grade ore.[8] A small trial shipment was sent to a metallurgical firm in the United States.

Albania.—The Spanish publication, Minería y Metalurgia, reported that Albanian authorities announced discovery of important deposits of chrome ore near Lake Shkodra (Lake Scutari).[9] The deposit was estimated to contain 500,000 tons of ore, but the grade was not specified.

Cuba.—Production of chromite advanced 20 percent over 1950 but was still far below that of earlier years. Virtually all of the output is of refractory grade for export to the United States.

Guatemala.—The only chromite-mining activity in Guatemala is that conducted by the Vanadian Corp. of America and vividly described.[10] The deposits, all small and widely scattered, lie within a serpentine belt in the province of Jalapa. The ore is mined from tunnels and transported by mules over 20 miles of steep, mountainous roads to the railway that takes the ore to Puerto Barrios. The ore is of very high metallurgical grade, some shipments reportedly carrying 59 percent chromic oxide and a 4.3 : 1 Cr–Fe ratio, with average boatload shipments running 53 percent Cr_2O_3 and a Cr–Fe ratio of 3.4 : 1. The ore is used at the company's Niagara Falls, N. Y., plant.

New Caledonia.—The French Pacific Islands produce metallurgical-grade ore of high quality, principally for export to the United States; much smaller tonnages are shipped to France, Norway, Sweden, and Australia. Although output in 1951 was only a few hundred tons less than peak production in 1949—88,792 metric tons—the new Calmet operation, with financial assistance from ECA and concessions of the French Government, is expected to increase the supply for American and French industries.

[1] In addition to countries listed, Bulgaria, Indochina, Iran, Sweden, and United Kingdom produce chromite, but data on output are not available; estimates by author of chapter included in total.
[2] Revised figure.
[3] Data not available; estimate by author of chapter included in total.
[4] Output from U. S. S. R. in Europe included with U. S. S. R. in Asia.
[5] Planned production as reported.
[6] Pakistan included with India, 1945–46.
[7] Estimate.

Philippines.—Production of chromite was at an alltime high in 1951, with excellent prospects for greater output in 1952. Production in 1951 (1950 shown in parentheses) was: Refractory grade, 301,835 metric tons (208,665) and metallurgical grade, 32,736 tons (41,846). The sole producer of refractory chromite was the Benguet Consolidated Mining Co., operating the Consolidated Mines at Masinloc, Zambales. Increased mill capacity, new storage bins, improved wharf facilities, and brisk demand from United States markets were expected to boost output in 1952.

The decrease in output of metallurgical chromite was attributed to the exhaustion of reserves of Misamis Chromite and the March 26, 1951, raid of dissidents on the Acoje Mines causing an estimated destruction of over half a million pesos. Mining was resumed in May. At year end the Acoje Mines was completing construction of a 1,000-ton-a-day concentrating mill.[11]

Southern Rhodesia and Union of South Africa.—These two countries are discussed together because the chrome activities of both are similar in many respects. The chromite deposits of both countries are landlocked, and the ore must be transported by truck and rail hundreds of miles to ports in Mozambique (Portuguese East Africa).

[11] American Embassy, Manila, Dispatch 835, Dec. 18, 1951 (unpublished).

Digitized by Google

Railings from Southern Rhodesia terminate at the Port of Beira and those from the Union of South Africa at Lourenço Marques. Ore from Southern Rhodesia is principally of metallurgical grade; that from the Union is mostly chemical, but there is also some metallurgical and refractory.

Africa has the largest known chromite reserves in the world, but the quantity available to the United States and the free world is directly proportional to the rate of flow to the stockpiles at Beira and Lourenço Marques. Chrome railings from both Southern Rhodesia and South Africa are subject to curtailment during certain seasons in favor of coal, tobacco, and other agricultural products.

Turkey.—The 602,220 metric tons of chromite produced in Turkey in 1951 was an alltime high for all countries in the world. Independent operations accounted for 73 percent of the total output and the Turkish Government-owned Eti Bank 27 percent. Considerable interest and expansion in chromite mining have resulted from United States determination to develop alternative sources of metallurgical chromite to offset the 1950 Russian embargo on shipments to the United States. The war in Korea and efforts to fulfill minimum National Stockpile objectives have created a brisk market for all grades of chromium ores. ECA funds have been used to stimulate the chromite industry of Turkey, and a large part of the resulting output has gone into the National Stockpile.

Exports of chromite from Turkey in recent years are shown in table 11.

TABLE 11.—Exports of chromite from Turkey, 1935–39 (average) and 1947–51, by destination, in metric tons [1]

Destination	1935–39 (average)	1947	1948	1949	1950	1951

Clays

By Brooke L. Gunsallus and B. V. Russ [1]

GENERAL SUMMARY

TOTAL clay production in 1951 increased 10 percent over 1950. Record highs made in 1950 for all six major classifications—china clay or kaolin, ball clay, fire clay, bentonite, fuller's earth, and miscellaneous clays—were exceeded in 1951.

Production of kaolin and ball clay each increased 7 percent in 1951 over 1950. All of the principal kaolin uses showed substantial increases except pottery, stoneware, and kiln furniture which registered decreases. Production of kaolin continued its uptrend that started in 1945, and that of ball clay in 1951 broke the previous high set in 1950, with pottery manufacturers by far the principal consumers. All users of ball clay, as classified herein, showed increases over 1950.

TABLE 1.—Salient statistics of clay in the United States, 1950–51

	1950		1951	
	Short tons	Value	Short tons	Value
Domestic clay sold or used by producers:				
Kaolin or china clay	1,750,858	$23,943,782	1,866,299	$25,324,554
Ball clay	324,414	3,980,167	344,981	3,725,930
Fire clay, including stoneware clay	9,535,867	29,019,372	11,852,517	48,740,596
Bentonite	973,833	8,560,669	1,218,868	13,006,645
Fuller's earth	396,025	6,504,733	483,623	8,131,761
Miscellaneous clays	26,400,449	23,241,210	27,649,491	29,692,830
Total sold or used by producers	39,381,446	95,249,933	43,415,779	128,622,316
Imports:				
Kaolin or china clay	122,974	1,619,384	110,475	1,581,378
Common blue and Gross Almerode	34,974	345,274	35,613	360,319
Fuller's earth	237	3,685	405	7,929
Other clay	3,076	32,534	4,763	71,629
Total imports	161,261	2,000,877	151,256	2,021,255
Exports:				
Kaolin or china clay	28,261	509,376	36,435	671,058
Fire clay	74,693	704,016	101,146	1,028,719
Other clay (including fuller's earth)	135,166	3,784,343	185,963	5,744,490
Total exports	238,120	4,997,735	323,544	7,444,267

Except for a small decrease in 1949, bentonite output has increased each successive year for the past 13 years. In 1951 tonnage increased 25 percent and value 52 percent over 1950. The foundry and petroleum industries consumed most of the total tonnage, and use for rotary-

[1] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Digitized by Google

drilling mud, filtering and decolorizing oils, and foundry-sand bond increased.

Total production of fuller's earth increased 22 percent in 1951 over 1950, the previous record year. Mineral-oil refining, absorbent uses, insecticides, and rotary-drilling mud were all represented in the upward trend.

The production of fire clay in 1951 was 24 percent greater than in 1950 owing to the expansion of steel-mill and foundry facilities and the pent-up civilian and industrial demand for heavy clay products.

Price quotations of clay and clay products in 1951, as shown in trade papers, remained steady in most instances, but some followed a general uptrend.

Imports of kaolin in 1951 fell 10 percent below comparable 1950 figures and represented less than 6 percent of the total domestic consumption in 1951 compared to 7 percent in 1950.

Imports of ball clay (including common blue and Gross Almerode clays) increased less than 2 percent in tonnage and 4 percent in value. By far the greater part of the imports of kaolin and ball clay originated in the United Kingdom, although small quantities were imported from Canada and a very small amount of ball clay from Germany.

Exports of kaolin or china clay in 1951 (36,435 short tons) rose 29 percent over 1950, the same increase as in 1950 over 1949; 86 percent was shipped to Canada. Exports of fire clay in 1951 exceeded those in 1950 by 35 percent in tonnage and 46 percent in value, totaling 101,146 short tons valued at $1,028,719. Of the total, 78 percent was shipped to Canada; the remainder was distributed throughout the world.

CONSUMPTION AND USES

Heavy clay products in 1951 consumed 5 percent more clay than in 1950 and represented 55 percent of the total clay produced. Clays used in portland and other hydraulic cements in 1951 amounted to 18 percent of the output of all clays; refractories, 17 percent; paper filler and coating clays and rotary-drilling mud, 2 percent each; and filtering and decolorizing oils and pottery 1 percent each. The remainder was consumed for a large number of miscellaneous purposes.

Although most uses of clay increased in tonnage in 1951 compared with 1950, the following uses decreased: High-grade tile (13 percent), rubber (15 percent), chemicals (8 percent), filler other than paper or paint (5 percent), and plaster and plaster products (31 percent). Many uses showed substantial gains in 1951 over figures reported in 1950. The increases for some of the more important classifications were as follows: Paper filler and coating 7 percent, heavy clay products 5 percent, pottery 5 percent, refractories 33 percent, cement 10 percent, rotary-drilling mud 27 percent, insecticides and fungicides 13 percent, and filtering and decolorizing oils 25 percent.

CHINA CLAY OR KAOLIN

The upward trend in kaolin production that began in 1945 continued in 1951. Tonnage increased 7 percent over 1950, the previous record year. The value increase was 6 percent.

As has been the pattern for the past several years, the paper, rubber, pottery, and refractory industries were the principal consumers. Paper consumed 964,601 short tons (52 percent of the total kaolin) including 533,490 short tons for filler and 431,111 for coating. The rubber industry consumed 231,331 short tons (12 percent), refractories 200,236 short tons (11 percent), and pottery 141,733 (8 percent). The remainder (17 percent) was consumed for a wide variety of purposes, including cement, high-grade tile, fertilizers, chemicals, insecticides, paint filler or extender, calcimine, and linoleum. The following users reported increases: Paper filler 21 percent, refractories 28 percent, filtering and clarifying oils 78 percent, high-grade tile 18 percent, linoleum 3 percent, and paint 40 percent. Decreased consumption was reported for paper coating (7 percent), rubber (12 percent), chemicals (23 percent), insecticides and fungicides (4 percent), and plastic coating (31 percent).

TABLE 3.—Kaolin sold or used by producers in the United States, 1950–51, by States

State	Sold by producer		Used by producer		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1950						
Alabama, Florida, and North Carolina	59,049	$1,163,079			59,049	$1,163,079
California	(1)	(1)	(1)	(1)	22,657	309,995

[1] Included with "Other States."
[2] Includes States indicated by footnote 1 and Illinois, Nevada (1950 only), Utah, and Virginia.

Ten States reported kaolin sold or used by producers in 1951 compared with eleven in 1950; Nevada did not report in 1951. As has been the case for several years, Georgia ranked first with 70 percent of the total, the same as in 1950, South Carolina was second with 17 percent, and Pennsylvania was third with 4 percent. All States or groups of States for which statistics are published in table 3 show substantial gains in output in 1951 compared with 1950.

Quotations on Georgia kaolin, as reported in E&MJ Metal and Mineral Markets, for filler and ceramic grades were given in June 1951 (the last quotation in 1951) as $8.50 to $9.50 per short ton, depending upon grade, for crushed material and $13 to $17 for pulverized, in paper bags. North Carolina china clays, ceramic grades in bulk, carlots, were quoted at $20.25 to $22.25 per ton. Florida kaolins were quoted by the same source at $18.75 per ton for purified and crushed; $24.75 for washed and air-floated clays; and $38.50 for air-floated enamel grade. Crude Pennsylvania kaolin was quoted at $5 to $7.50 per ton and "purified" kaolin at $21 to $24. These prices were the same as those quoted in December 1950 and are substantially the same as those quoted in 1949.

Prices of imported china clay in December 1951 were quoted by the Oil, Paint and Drug Reporter as follows: White lump, carlots, ex dock (Philadelphia, Pa., and Portland, Maine), $20 to $40 per long ton; powdered, ex dock, in bags, $45 per net ton; and powdered, l. c. l., ex warehouse, $56. There has been very little change in price since October 1949. The average value of domestic kaolin sold or used as reported to the Bureau of Mines in 1951 was $13.57 per short ton compared with $13.68 for 1950 and $13.43 for 1949.

Imports of kaolin for 1951 decreased 10 percent from 1950 and represented only 6 percent of total domestic consumption in 1951 compared with 7 percent in 1950 and 5 percent in 1949. Of 1951 imports, totaling 110,475 short tons, 99 percent came from the United Kingdom and the remainder from Canada, France, Italy, and Australia.

Exports of kaolin or china clay in 1951 rose 29 percent over 1950 to 36,435 short tons, of which 86 percent was shipped to Canada. Small tonnages also were sent to Mexico, Central and South America, Europe, Union of South Africa, Japan, Indonesia, and Australia.

J. M. Huber Corp. published a book on the properties and industrial uses of kaolin, with emphasis on the applications of kaolin to synthetic rubber and machine coating of paper. Reference also is made to other important applications, such as ceramics and insecticides.[2]

Viscosity control of concentrated clay suspensions was discussed, giving special attention to kaolins. The viscosity of clays in concentrated suspension depends to a large extent on the shape of the particles and on the composition with respect to particle size.[3]

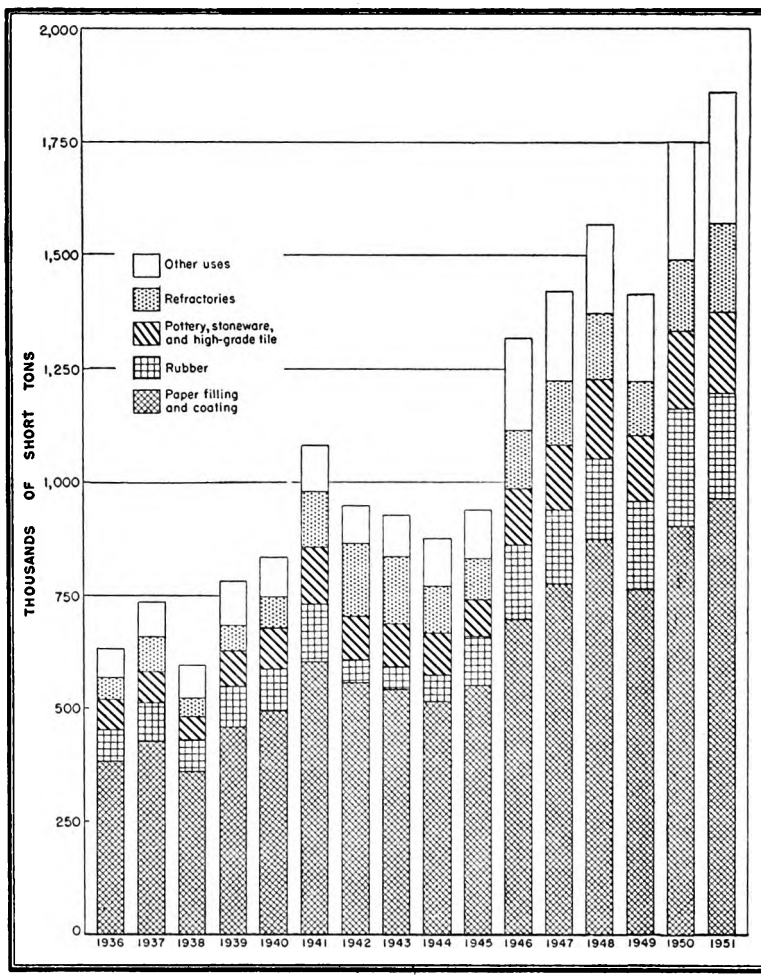

FIGURE 1.—Kaolin sold or used by domestic producers for specified uses, 1936–51.

BALL CLAY

Ball-clay production in 1951 set a record for tonnage, although the value decreased 6 percent compared with 1950. For the ninth consecutive year, Tennessee was the leader in tons produced, with 56 percent of the United States total. Kentucky ranked second, with 32 percent. Other leading States, in order of tons produced, were Maryland, Mississippi, and New Jersey. Compared to 1950 Kentucky and Tennessee each increased tonnage produced 5 percent in 1951.

The pottery industry consumed 78 percent of the ball clay produced in 1951 compared to 79 percent in 1950. Ball clay used in making whiteware increased 5 percent, and the quantities used in high-grade tile, architectural terra cotta, and enameling increased over the

Digitized by Google

previous year. In 1951 high-grade tile was 12 percent, refractories 6 percent, and miscellaneous smaller uses 4 percent of the total national output.

TABLE 5.—Ball clay sold by producers in the United States, 1949–51, by States

State	1949		1950		1951	
	Short tons	Value	Short tons	Value	Short tons	Value
Kentucky	89, 281	$1, 076, 531	105, 690	$1, 325, 161	111, 215	$1, 411, 175
Maryland, Mississippi, and New Jersey	27, 265	327, 427	34, 290	424, 480	39, 575	532, 113
Tennessee	132, 337	1, 660, 481	184, 434	2, 230, 526	194, 191	1, 782, 642
Total	248, 883	3, 064, 439	324, 414	3, 980, 167	344, 981	3, 725, 930

Price quotations appearing in E&MJ Metal and Mineral Markets in 1951, unchanged from 1950 and 1949 quotations, were as follows: Tennessee crude ball clay, $10 per short ton, and air-floated and pulverized, $19.50 per ton; Maryland—shredded, in bulk, $7 to $9, and air-floated, in bags, $14 to $17.50 per ton. No quotations on Kentucky ball clay in 1951 or 1950 were given in E&MJ Metal and Mineral Markets. In 1951 the average value per ton for ball clay as reported by producers to the Bureau of Mines was $10.80 compared with $12.27 in 1950 and $12.31 in 1949. In 1951 the average price per ton for Tennessee was $9.18; for Kentucky, $12.69, and for Maryland, Mississippi, and New Jersey, $13.45.

Imports of common blue and ball clay and Gross Almerode clays in 1951 increased less than 2 percent in tonnage and 4 percent in value compared with 1950. Unmanufactured blue and ball clays represented the major share of imports; United Kingdom supplied 84 percent of this classification and virtually all the imports of manufactured blue and ball clay. Small tonnages of imports of blue and ball clays came from Canada and Germany. Imports of Gross Almerode clays from United Kingdom and Germany totaled 80 and 15 tons, respectively. Exports, if any, are not separately shown in official foreign trade returns.

FIRE CLAY

The largest annual tonnage in the history of the fire-clay industry was sold or used in 1951, exceeding the previous high year of 1948 by 20 percent and 1950 by 24 percent. An expanded national economy and increased activity in the refractory and construction industries beginning in 1950 and carrying over into 1951 were the governing factors effecting the increase.

The principal uses of fire clay in 1951 were in refractories manufacture—6,892,722 short tons (34-percent increase over 1950)—and heavy clay products—4,615,634 short tons (15-percent increase over 1950). Refractories and heavy clay products use, combined, comprised 97 percent of the total tonnage output in 1951 compared with 96 percent in 1950. About 1 percent was consumed in manufacturing high-grade tile, a similar amount in chemicals, and the remainder in a wide variety of uses. The principal refractory use of fire clay is for the

Digitized by Google

manufacture of fire brick and block; this took 5,635,296 tons in 1951, a 45-percent increase over 1950. Several less important uses, such as high-grade tile, architectural terra cotta, and chemicals, decreased in 1951 compared with 1950. No consumption of fire clay by the rubber industry was reported in 1951.

TABLE 6.—Fire clay, including stoneware clay, sold or used by producers in the United States, 1950–51, by States [1]

State	Sold by producer		Used by producer		Total

[1] Includes stoneware clay as follows: 1950—105,147 tons, $235,063; 1951—85,331 tons, $271,625.
[2] Included with "Other States."
[3] Includes diaspore and burley clay as follows: 1950—diaspore, 40,750 tons, $488,464; burley, 53,571 tons, $334,299. 1951—diaspore, 45,020 tons, $704,151; burley, 73,781 tons, $745,032.
[4] Includes States indicated by footnote 2 above and Delaware (1950 only), Idaho, Iowa, Kansas, Massachusetts, Michigan, Minnesota, Mississippi, Montana, Nebraska, Nevada, New Mexico, North Dakota, Oregon, and South Carolina.

In 1951 Ohio ranked first in fire-clay output, followed by Pennsylvania, Missouri, West Virginia, Kentucky, California, and Indiana. These 7 States supplied 78 percent of the total. The remainder was produced in 24 States in 1951 (25 in 1950; Delaware did not report in 1951). Of the 17 principal producing States shown in table 6, Indiana, Utah, and Washington reported decreases, and the other 14 reported increases.

Price quotations on fire clay do not appear in trade journals; however, the average realization per ton from sales reported to the Bureau

Digitized by Google

of Mines by producers indicated that the average value of fire clay sold in 1951 was $3.22 compared with $3 in 1950 and $2.91 in 1949. The average value of all fire clay, including sales and captive tonnage, was $4.11 in 1951 compared to $3.04 in 1950, and $2.96 in 1949. Quotations on brick manufactured from fire clay were reported in 1951 in E&MJ Metal and Mineral Markets (1950 price in parentheses) as follows: Missouri, Kentucky, and Pennsylvania, first quality, $116.50 per thousand ($116.60), and second quality, $99.60 per thousand ($99.60); and Ohio firebrick, intermediate grade, $88 per thousand ($83), and second grade $79.20 per thousand ($79.20).

Imports of fire clay are not shown separately in foreign trade statistics. Exports of fire clay in 1951 were greater by 35 percent in tonnage and 46 percent in value than in 1950 and totaled 101,146 short tons valued at $1,028,719. Canada took 88 percent of the total exports and Mexico 7 percent. The remainder (5 percent) comprised small tonnages to 40 destinations in Central and South America, Europe, Asia, and Africa.

The geology, mineralogy, petrography, known deposits, and present and potential reserves of refractory clays of Maryland were discussed.[4]

BENTONITE

Bentonite production broke all records in 1951. According to reports of producers, there was a 25-percent tonnage increase and 52-percent value increase in 1951 over 1950. Increased activity in oil-well drilling and overall expansion in the foundry industry were responsible for the large output of bentonite.

The foundry and petroleum industries consumed 94 percent of the total tonnage; of this, rotary-drilling mud represented 38 percent (460,261 short tons), filtering and decolorizing oils 33 percent (397,940 short tons), and foundry-sand bond 23 percent (282,753 short tons). The remainder (77,914 short tons) went into a wide variety of uses. Bentonite used for rotary-drilling mud increased 29 percent in 1951 over 1950, filtering and decolorizing oils 34 percent, and foundry-sand bond 12 percent.

The same 9 States reported bentonite production in 1951 as in 1950. Increases in tonnage were noted for Arizona, California, Colorado, Mississippi, South Dakota, Texas and Wyoming, and decreases for Idaho and Utah.

TABLE 7.—Bentonite sold or used by producers in the United States, 1949–51, by States

State	1949		1950		1951

Digitized by Google

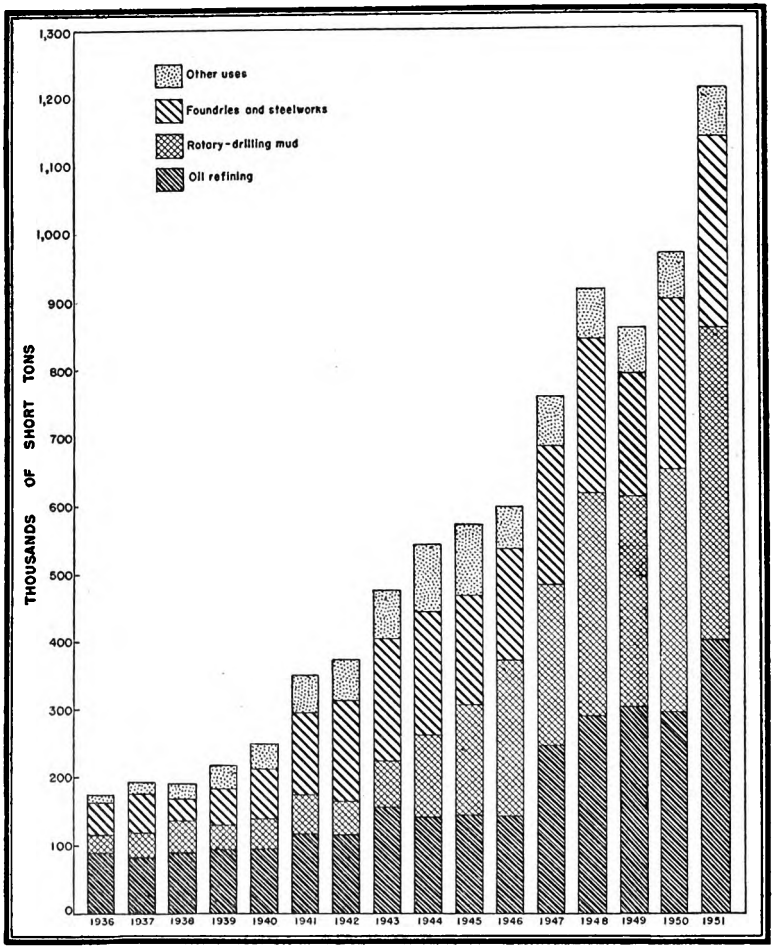

FIGURE 2.—Bentonite sold or used by domestic producers for specified uses, 1936–51.

The Wyoming-South Dakota district supplied 58 percent of the total bentonite production in 1951 (Wyoming 38 percent and South Dakota 20 percent) compared with 60 percent in 1950. Texas furnished 3 percent of the total, the same as it had each year since 1948. Trends in sales for principal uses are shown in figure 2.

In 1951 Wyoming bentonite was quoted in E&MJ Metal and Mineral Markets as follows: Dried, crushed, in bulk, $9 per ton; and 200-mesh, pulverized, in 100-pound bags, $12.50. Oil-well grade was quoted at $14 per ton. The average value per ton as reported by producers to the Bureau of Mines in 1951 increased to $10.67 compared with $8.79 in 1950 and $8 in 1949.

Less than 50 tons of bentonite was imported in 1951, mostly from Canada, with a token amount from Italy.

Digitized by Google

Exports of bentonite are not shown separately in foreign trade statistics but are included under the blanket classification of "Other clays or earths, not specifically provided for." It is understood, however, that some domestic producers export part of their production to destinations throughout the world.

Control tests for the gel-forming properties of bentonite as well as bentonite determination in ceramic mixtures were discussed.[5]

FULLER'S EARTH

The production of fuller's earth continued to rise in 1951, increasing 22 percent over 1950, the previous record year.

In 1951 mineral-oil refining was still the largest single consumer, although it did not pace the overall rise in national output. Consumption for this use in 1951 represented 36 percent of total production compared with 40 percent in 1950 and 47 percent in 1949. It was the consensus of opinion that this trend resulted, in part, from improved methods of oil refining and marketing of a higher quality of fuller's earth.

Absorbent uses took 97,465 tons (20 percent of the total compared with 21 percent in 1950 and 22 percent in 1949); insecticides 86,339 tons (18 percent compared with 18 percent in 1950 and 12 percent in 1949); rotary-drilling mud 79,469 tons (16 percent compared with 10 percent in 1950 and 9 percent in 1949); and vegetable-oil refining 20,251 tons (4 percent compared with 5 percent in 1950 and 6 percent in 1949). The remainder was used in other filtering and clarifying, binders, and other unspecified uses.

Nevada was the only State that showed a tonnage decrease in 1951 over 1950. The Florida-Georgia area furnished 62 percent of the total tonnage produced in 1951, the same as in 1950, while production in Texas supplied 29 percent compared with 28 percent in 1950.

As reported by E&MJ Metal and Mineral Markets in 1951, quotations on Georgia and Florida fuller's earth remained unchanged in 1951 from those of 1950 and 1949. Prices were as follows: 14- to 30-mesh, $14 per short ton; 30- to 60-mesh, $14.50; 100-mesh up, $7; and 200-mesh up, $10. The average value of fuller's earth sold or used, as reported to the Bureau of Mines by producers, was $16.81 per ton in 1951 compared with $16.42 in 1950 and $16.20 in 1949.

TABLE 8.—Fuller's earth sold or used by producers in the United States, 1949–51, by States

State	1949		1950		1951	
	Short tons	Value	Short tons	Value	Short tons	Value
Florida and Georgia	181,993	$3,194,551	247,390	$4,273,890	299,071	$5,258,330
Illinois	9,104	118,647				
Texas	100,745	1,242,558	112,466	1,393,773	142,273	1,952,304
Other States [1]	29,064	643,886	36,169	837,070	42,279	921,127
Total	320,906	5,199,642	396,025	6,504,733	483,623	8,131,761

[1] Includes California, Mississippi, Nevada, Tennessee, and Utah.

Imports of fuller's earth in 1951 totaled 405 short tons, all from the United Kingdom except a small amount from Canada. Exports are not given separately in official foreign statistics. Reports from the producers to the Bureau of Mines, however, indicated exports of approximately 35,000 short tons in 1951 compared with 16,400 tons in 1950. Destinations reported include North America, Central and South America, West Indies, several European nations, Bahrein Island, Saudi Arabia, and the Philippines.

The characteristics, activation and uses of fuller's earth were discussed.[6]

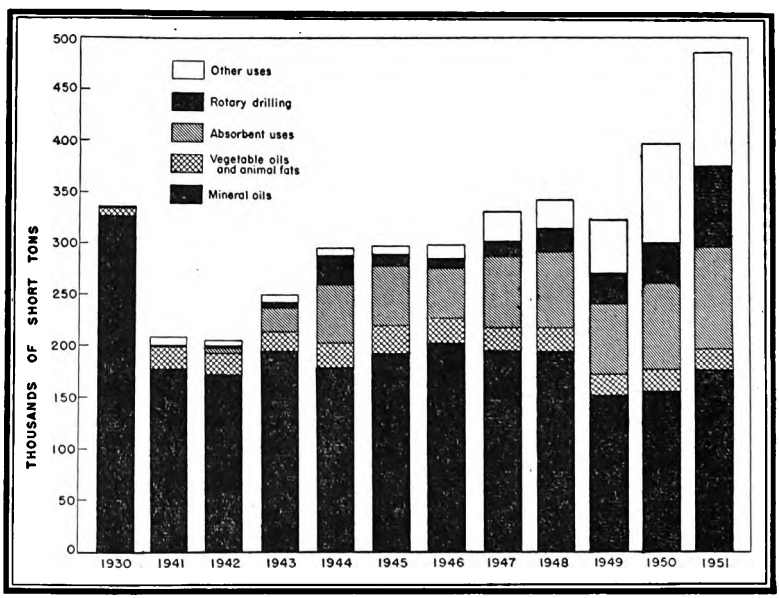

FIGURE 3.—Fuller's earth sold or used by producers for specified uses, 1930 and 1941–51.

MISCELLANEOUS CLAYS

This section includes statistics for the large-tonnage clays and shales, other than those discussed in the preceding pages, that are used in the manufacture of heavy clay products and portland cement. With these clays are grouped small tonnages of slip clay, oil-well drilling mud, pottery clay, and other clays that cannot be clearly identified with one of the types discussed separately in this chapter.

The demand for clay products and cement in the construction field that was evident in 1950 carried over into 1951. For this reason production of miscellaneous clays increased 5 percent in tonnage over 1950. In 1951, 69 percent of the total miscellaneous clays were used in manufacturing heavy clay products and 28 percent in cement. Tonnage consumed in heavy clay products was 3 percent more than

[6] Mineral Information Service, Department of Natural Resources, State of California, Absorbent Clay: Vol. 5, No. 7, July 1951, pp. 1–2.

Digitized by Google

in 1950, and quantities used in cement manufacture rose 10 percent. Captive tonnage, or clay produced by the mine operators for their own use in manufacturing brick, tile, cement and other end products and marketed for the first time as such, amounted to 96 percent (the same as for the past 5 years) of all miscellaneous clays and shales (figures for which are given in this section). The average value per ton of the miscellaneous clays sold as crude or prepared clay in 1951 was $2.05. Some special types of clay included under the "miscellaneous" clay classification, however, sold for much higher amounts. The value of the captive tonnage was computed from individual estimates that generally were around $1 per ton.

Miscellaneous clays, including shales and the so-called common or surface clays, are of widespread occurrence, and workable commercial deposits were reported in all States in 1951 except Nevada and Rhode Island. Three States—California, Illinois, and Ohio—reported tonnage production exceeding 2 million short tons each. Other States reporting a production of over 1 million tons were, in order of output:

[1] Includes slip clay as follows: 1950-51—Indiana, Michigan, and New York; figures cannot be shown separately. Purchases by portland-cement companies of common clay and shale: 1950—555,910 tons, estimated at $466,600; 1951—658,450 tons, estimated at $660,936.

[2] Includes the following: Common clay and shale used by portland-cement companies: 1950—6,453,777 tons, estimated at $4,840,342; 1951—7,060,473 tons, estimated at $7,205,289.

[3] Included under "Undistributed."

[4] Figures include Alabama (1951 only), Arizona, Delaware, District of Columbia, Florida, Idaho, Mississippi (1951 only), Nevada (1950 only), North Dakota, South Dakota, Tennessee (1951 only), Vermont, Virginia, and States indicated by footnote 3.

Pennsylvania, Texas, New York, Michigan, North Carolina, Georgia, Alabama, and Indiana. Of the States for which data are shown in table 9, 21 reported increases and 17 decreases in output in 1951 compared with 1950.

Increased manufacturing capacity resulting from new plants and efficient alterations in existing plants of the vitrified clay sewer pipe industry helped to increase the demand for miscellaneous clays and shales.[7]

HEAVY CLAY PRODUCTS

The demand for structural clay products in 1951 with relation to 1950 was varied; some products showed increases and others decreases. The increases in shipments in 1951 over 1950 were as follows: Drain tile, 4 percent; hollow facing tile, 8 percent; glazed and unglazed floor and wall tile, 11 percent. The decreases were: Unglazed brick (common and face), 3 percent; unglazed structural tile, 11 percent; vitrified clay sewer pipe, 1 percent.

The total value of the principal structural clay products in 1951 increased 8 percent to $352,000,000 from $327,000,000 in 1950.

TABLE 10.—Shipments of principal structural clay products in the United States, 1949–51 [1]

Product and unit of quantity	1949		1950		1951	
	Quantity	Value (thousand dollars)	Quantity	Value (thousand dollars)	Quantity	Value (thousand dollars)
Unglazed brick (common and face) M stand. brick	5,251,633	129,179	6,486,332	164,470	6,306,561	170,743
Unglazed structural tile short tons	1,259,445	14,060	1,316,972	14,896	1,166,879	14,098
Vitrified clay sewer pipe do	1,349,598	44,641	1,567,664	53,402	1,554,711	58,238

Glazed and unglazed floor and wall tile and accessories, including quarry tile M square feet	93,115	43,905	127,302	61,579	141,322	71,277

[1] Compiled from information furnished by the Bureau of the Census, U. S. Department of Commerce.

The value of shipments of all branches of the clay-refractories industry shown in table 11 followed the same pattern of increases in 1951 over 1950 as 1950 had shown over 1949. Overall expansion in the steel and foundry industries (due for the most part to the national emergency) augmented the demand for clay refractories. The value of shipments of firebrick (except superduty) was $78,562,000, 37 percent over 1950; superduty fire-clay brick, $16,158,000, 60 percent over 1950; and ladle brick, $14,652,000, 21 percent over 1950.

A new trade association, the Refractories Institute, was formed by the members of the refractory industry to promote demand for the products of the industry and to spur additional research with the objective of further improving products and processes. The headquarters are in Pittsburgh, Pa.[8]

Harbison-Walker Refractories Co. approved plans for a new plant at Fairfield, near Birmingham, Ala., for the production of fire brick and other refractories for steel plant service. It was reported the cost would approximate 4 million dollars.[9]

Expansion and plant modernization in the refractories industry kept pace with the demand for all types of refractory products.[10]

Plant modernization and improved manufacturing methods were described in several published articles, especially for structural clay products,[11] and pottery.[12] The expansion of the ceramic industry helped to increase the consumption of clays and shales.

TECHNOLOGY

Since January 1, 1950, the Structural Clay Products Research Foundation had been engaged in a full-scale industry-wide research program on new and improved clay products, and new methods of manufacture and construction.[13]

The National Clay Pipe Research Corp. was conducting a general research program on the production of vitrified clay pipe. One phase of this program was a study by the Ohio State University Research Foundation in reference to firing and cooling shrinkage behavior of structural clay bodies. Many materials tested are used in the production of heavy clay products other than vitrified clay pipe.[14]

An investigation was carried out at the Department of Ceramic Engineering, University of Illinois, designed to determine the effects of different heating ratio upon the shrinkage characteristics of clays and shales. The results showed a similarity in the shrinkage behavior of shales and fire clays.[15]

A study was conducted to determine the thermal reactions taking place during the firing of brick made from fire clays and shales. The object of the study was to obtain fundamental data needed for a better understanding of reactions that occur within a brick during firing.[16]

The corrosion resistance of high-purity refractories when exposed to molten glass of ordinary colorless bottle-glass composition was investigated. The refractory mixtures were made from kaolin, calcined alumina, and flint.[17]

Digitized by Google

A completely new clay-preparation system was installed in the pottery industry that reduced the cost of preparation 20 to 25 percent.[18]

Barium carbonate as a means of preventing the formation of scum and efflorescence on brick was discussed, along with the sulfide content of clay which must be considered in calculations for barium treatment.[19]

The Hanley Co., with executive offices in New York City and structural clay-products plants in Pennsylvania, established a research fellowship at the Mellon Institute in Pittsburgh, Pa. It is long-range in character and has for its purpose fundamental research and development work in the technology of structural clay products.[20]

Data on refractory materials in southern Ohio and northeastern Kentucky were given, such as geology, analyses, uses, and estimated reserves.[21]

The American Iron and Steel Institute and the American Ceramic Society published a comprehensive refractories bibliography, covering the literature and United States and foreign patents from 1928 to 1947, inclusive.[22]

A new laboratory was built at the Armour Research Foundation, Illinois Institute of Technology, for research to develop stronger, cheaper, and lighter concrete block. Concrete units using expanded clay and shale lightweight aggregates developed by the foundation were to be studied.[23]

New lightweight aggregate plants were built to utilize residual clay in North Carolina [24] and shale in Tennessee.[25]

The Minnesota Geological Survey conducted investigations on the possibilities of using Minnesota clays and shales as raw materials for production of lightweight concrete aggregates.[26] Relation of chemical properties to the bloating of clay was discussed.[27]

It was estimated that extraction of a million tons per year from the known deposits of china clay or kaolin in Devon and Cornwall, England, would not exhaust the supply in a century.[28]

Data on the economic importance of Philippine clays were outlined as to classification, composition and uses in ceramic products.[29]

Fire-clay resources of Japan were summarized for the General Headquarters, Supreme Commander for the Allied Powers. Supply and demand of fire clay, by kinds, were discussed, as well as potential reserves.[30]

Coal—Bituminous and Lignite[1]

By W. H. Young, R. L. Anderson, and E. M. Hall

GENERAL SUMMARY

THE BITUMINOUS-COAL and lignite industry showed signs of considerable improvement in 1951; production, consumption, exports, average value, mechanization, and productivity increased over 1950.

Production.—The output of soft coal in 1951—534 million tons[2]—was 3 percent higher than the 516 million tons produced in 1950. The smaller amount of time lost by strikes in 1951, compared to 1950, largely explains the increase. According to the Bureau of Labor Statistics, 887,000 man-days were lost due to strikes in 1951 compared to 9,320,000 man-days in 1950.

There was virtually no seasonal decline in production in 1951, owing largely to increased exports to Europe. Throughout most of the year production exceeded 10 million tons a week, except when output was reduced because of holidays. The man-days lost by strike was the lowest since 1942.

Trend of Men Working Daily.—The average number of men working daily at bituminous-coal and lignite mines in 1951 decreased to 372,897 from 415,582 in 1950.

Index to Capacity.—As it is not possible for all mines to operate every working day in the year, a conservative figure of 280 days for calculating potential capacity was suggested some years ago by the coal committee of the American Institute of Mining and Metallurgical Engineers. (*See* Minerals Yearbook, 1935, pp. 631–632.) The average output per day worked in 1951 was 2,628,890 tons, which (if applied to 280 days) gives an annual potential output of 736 million tons, compared with the actual production of 534 million.

Mechanization.—More coal was loaded mechanically at underground mines in the United States in 1951 than in 1950; the percentage mechanically loaded increased from 69 percent of total underground output in 1950 to 73 percent in 1951. Sales of underground loading equipment, in terms of capacity, were approximately the same as in 1950.

Mechanical Cleaning.—The total capacity of mechanical-cleaning equipment sold for use at bituminous-coal mines in 1951 was estimated at 13,900 tons of cleaned coal per hour, a 14-percent increase over the previous year.

[1] Data for both 1950 and 1951 are final.
[2] Throughout this chapter, "tons" refers to net tons of 2,000 pounds, except that the world table is in metric tons of about 2,205 pounds.

TABLE 1.—Salient statistics of the bituminous-coal and lignite industry in the United States,[1] 1950–51

[All tonnage figures represent net tons of marketable coal and excludes washery and other refuse]

	1950	1951	Change from 1950 (percent)
Production	516,311,053	533,664,732	+3.4
Consumption in the United States	454,202,000	468,904,000	+3.2
Stocks at end of year:			
Industrial consumers and retail yards	72,516,000	76,636,000	+5.7
Stocks on upper Lake docks	6,206,997	5,542,891	−10.7
Imports and exports:[2]			
Imports	346,706	291,536	−15.9
Exports	25,468,403	56,726,155	+122.7
Price indicators (average per net ton):			
Average cost of railroad fuel purchased, f. o. b. mines[3]	$4.49	$4.54	+1.1
Average cost of coking coal at merchant coke ovens	$9.39	$9.51	+1.3
Average retail price[4]	$16.48	$16.87	+2.4
Average railroad freight charge per net ton[3]	$3.09	$3.16	+2.3
Average value f. o. b. mines	$4.84	$4.92	+1.7
Underground loading machinery sold:			
Mobile loading machines (number)	289	287	−.7
Scrapers (number)	1	4	+300.0
Conveyors, including those equipped with duckbills (units)	316	297	−6.0
"Mother" conveyors (units)	132	114	−13.6
Surface stripping	123,466,564	117,617,676	−4.7
Mechanically loaded underground	272,724,612	304,255,921	+11.6
Mechanically cleaned	198,698,518	240,009,808	+20.8
Number of mines	9,429	8,009	−15.1
Average number of days worked	183	203	+10.9
Average number of men working daily[5]	415,582	372,897	−10.3
Production per man per day	6.77	7.04	+4.0
Fuel efficiency indicator:			
Pounds of coal per kw.-hr. at electric power plants[6]	1.19	1.14	−4.2

[1] Includes Alaska. There was no recorded production in Hawaii and Puerto Rico.
[2] U. S. Department of Commerce.
[3] Interstate Commerce Commission.
[4] Bureau of Labor Statistics, U. S. Department of Labor.
[5] Equals man-shifts divided by number of active days.
[6] Federal Power Commission.

Consumption.—Seven classes of consumers used more coal in 1951 than in 1950, whereas two classes decreased their consumption. The total consumption in 1951 was approximately 15 million tons more than in 1950. Table 44 shows trends in consumption for the major classes of consumers.

Trends of Fuel Efficiency.—During 1951 electric public-utility power plants attained increased fuel efficiency.

Competition With Oil and Gas.—Soon after World War II, increased competition developed among the fuels, with numerous reports of conversion from coal to fuel oil and gas.

Electric-power utilities consumed 15 percent more bituminous coal, 15 percent less fuel oil, and 21 percent more gas in 1951 than in 1950.

Class I railroads decreased their consumption of coal 11 percent in 1951 from 1950 and increased their purchases of fuel oil and Diesel oil 5 percent during the same period.

The manufacture of domestic coal-burning equipment is reflected in statistics published by the Bureau of the Census. Factory sales

Digitized by Google

of domestic stokers for burning bituminous coal decreased from 13,102 (revised figure) in 1950 to 12,386 in 1951. Shipments of domestic oil burners, boiler-burner units, and furnace-burner units decreased from 879,922 (revised figure) in 1950 to 658,714 in 1951.

Stocks.—The reserve supply of bituminous coal and lignite in the hands of industrial consumers and retail coalyards increased from 72.5 million tons at the beginning of 1951 to 76.6 million tons at the close. The day's suppply of stocks increased from 50 to 56. Stocks on the upper Lake docks decreased 664,106 tons from January 1 to December 31, 1951.

SOURCES OF DATA

Data for 1951 are final and are based upon detailed annual reports of production and mine operation furnished by the producers. As in previous years, all but a small percentage of the output was covered by the reports submitted. For the remaining output not directly reported—consisting chiefly of small mines—it has been possible to obtain reasonably accurate data from the records of the State mine departments, which have statutory authority to require such reports, or, in a few instances, from railroad carloadings. Production includes all marketable coal and excludes washery and other refuse.

In accordance with the practice followed by the Bureau of Mines in previous years, the statistics in this report relate to mines having an output of 1,000 tons a year or more and do not attempt to include many small mines producing less than 1,000 tons a year.

As in previous years, these data include all coal produced in Alaska and all that produced in the United States except Pennsylvania anthracite.

PRODUCTION BY MONTHS AND WEEKS

Tables 4 to 7 summarize the statistics of monthly and weekly production of bituminous coal and lignite. The estimates given are based upon the latest information available and differ in some instances from the current figures published in the Weekly Coal Reports.

TABLE 4.—Bituminous-coal and lignite production in the United States,[1] 1950–51, with estimates by months

Month	1950			1951		
	Production (thousands of net tons)	Maximum number of working days	Average production per working day (thousands of net tons)	Production (thousands of net tons)	Maximum number of working days	Average production per working day (thousands of net tons)
January	31,351	25	1,254	51,531	26	1,982
February	12,337	24	514	39,990	24	1,666
March	54,049	27	2,002	44,713	27	1,656
April	47,004	24.5	1,919	41,888	24.2	1,731
May	46,162	26.5	1,742	43,281	26.4	1,639
June	46,213	26	1,777	43,448	25.5	1,704
July	35,396	25	1,416	34,007	20.2	1,684
August	50,487	27	1,870	47,072	27	1,743
September	47,653	25	1,906	42,853	24	1,786
October	51,805	26	1,993	51,675	27	1,914
November	45,906	25	1,836	49,207	24.8	1,984
December	47,948	25	1,918	44,000	25	1,760
Total	516,311	306.0	1,687	533,665	301.1	1,772

[1] Includes Alaska.

TABLE 5.—Coal production in the United States, 1950, by States, with estimates by months, in thousands of net tons

[Totals for year are based on final complete returns from all operators known to have produced 1,000 tons and over per year. In most cases monthly apportionment is based on current records of railway carloadings and waterway shipments; in some States upon direct tonnage reports by operators to State mine departments]

State	January	February	March	April	May	June	July	August	September	October	November	December	Total

[1] Includes coal loaded at mine directly into railroad cars or river barges.

[2] Includes coal used by mine employees, taken by locomotive tenders at tipple, used at mine for power and heat, coal transported from mine to point of use by conveyor or tram, coal made into beehive coke at mine and all other uses at mine.

[3] Value received or charged for coal, f. o. b. mine, including selling cost. (Includes a value for coal not sold but used by producer, such as mine fuel and coal coked [not coke] as estimated by producer at average prices that might have been received if such coal had been sold commercially.)

[1] Percentages for 1900 to 1913, inclusive, are of total production, as a separation of strip and underground production is not available for those years.
[2] For 1906 to 1926, inclusive, these percentages are exclusive of coal cleaned at central washeries operated by consumers.
[3] Data not available.
[4] Bureau of Labor Statistics, U. S. Department of Labor.
[5] Average number of men working daily.

TABLE 19.—Number of underground bituminous-coal mines and number of haulage units in use, in the United States, in selected years [1]

Units	1924	1946	1948	1949	1950	1951
Underground mines	7,352	5,888	7,108	6,798	7,559	6,225
Locomotives:						
Trolley	[2] 12,765	14,110	14,617	14,090	13,822	13,327
Battery	1,515	1,011	904	928	949	900
Other types	443	110	74	59	62	51
Total	14,723	15,231	15,595	15,077	14,833	14,278
Rope haulage units:						
Portable	([3])	4,084	3,886	3,904	4,225	3,875
Stationary	([3])	1,009	1,044	1,073	1,037	916
Total	649	5,093	4,930	4,977	5,262	4,791
Shuttle cars:						
Cable reel	([3])	([3])	([3])	2,144	2,782	3,191
Battery	([3])	([3])	([3])	623	512	567
Total	([3])	([3])	([3])	2,767	3,294	3,758
Mother conveyors	([3])	457	755	860	1,013	1,094
Animals	36,352	10,185	10,834	10,313	10,033	7,478

[1] Exclusive of lignite and Virginia semianthracite mines in 1946, 1948, and 1949. Detailed data, by States, published in Bureau of Mines Mineral Market Report 2102, Oct. 27, 1952.
[2] Includes combination trolley and battery locomotives.
[3] Data not available.

MECHANICAL LOADING

Bituminous coal and lignite mechanically loaded in underground mines amounted to 304.3 million tons in 1951, or 73 percent of the total underground output.

Mechanical loading equipment used in underground bituminous-coal and lignite mines is divided into two types, "machines" and "conveyors." Machines are devices that virtually eliminate hand shoveling; they include mobile loaders, continuous mining machines, augers, scrapers, and conveyors equipped with duckbills or other self-loading heads. Conveyors are devices that greatly reduce the labor in hand shoveling; they include hand-loaded face conveyors and pit-car loaders.

Sales of Mechanical Loading Equipment.—Shipments of mechanical loading equipment for underground use in coal mines in the United States, in terms of capacity, were approximately the same in 1951 as in 1950. Table 27 shows the reported sales of mechanical loading equipment to bituminous-coal and lignite operators, by type of equipment and the number of manufacturers reporting for 1944–51.

Table 28 shows loading equipment, "mother" conveyors, and shuttle cars sold in 1950–51 for use in bituminous-coal and lignite mines, by States.

Extent of Mechanical Loading.—Mobile loaders, continuous mining machines, and augers handled 83 percent of the underground tonnage that was mechanically loaded in 1951. Table 29 shows the tons and percentage handled by each type of equipment in 1950 and 1951.

During 1951, in underground bituminous-coal and lignite mines, a combined total of 4,410 mobile loaders, continuous mining machines, and augers was in use, and the average annual output per machine was 57,293 tons; self-loading conveyors averaged 11,178; scrapers, 5,734; and hand-loaded face conveyors, 9,627 tons per unit per year.

Mechanical Loading by States.—West Virginia has been the leading producer of mechanically loaded coal since 1939. During 1951 West Virginia produced 115.7 million tons of mechanically loaded coal or 38 percent of the total bituminous coal and lignite mechanically loaded in the United States. Pennsylvania was second in production of coal mechanically loaded, followed by Kentucky, Illinois, and Ohio. These 5 States produced 85 percent of the total output of underground, mechanically loaded bituminous coal in the United States in 1951.

Detailed data, by States, on the number of mines, mechanical loading units, and production of coal mechanically loaded compared with the total production at mines using mechanical loading devices are given in tables 31 and 32. Comparative changes in underground mechanical loading in 1950–51, by States, are shown in table 30.

Table 15 shows bituminous-coal and lignite tonnage mined by stripping compared with underground hand-loaded and machine-loaded tonnage, as well as productivity and percent mined at strip and underground mines, by States, for 1951.

MECHANICAL CLEANING

Bituminous coal mechanically cleaned in 1951 totaled 240.0 million tons, or 45 percent of the entire output.

Mechanical cleaning by wet methods includes jigs, concentrating tables, classifiers, launders, dense-medium processes, flotation, and any combinations of these six methods.

Pneumatic methods of coal cleaning include air tables, air flow, air sand, and any combination of these three methods.

Tables 33, 34, 37, and 38 include mechanical-cleaning data on all coal mined in the United States except Pennsylvania anthracite. Tables 35 and 36 are on the same basis but do not include consumer-operated plants. The percentage of total production mechanically cleaned in 1906–51 is shown in table 13.

Consumer-operated plants include those owned by steel companies that receive coal (usually from affiliated companies), clean it, and then consume it directly at the plant.

Types of Cleaning Equipment.—The tonnage of bituminous coal cleaned by wet-washing methods was 221.4 million tons in 1951—a 21-percent increase over 1950. The quantity cleaned by pneumatic methods was 18.5 million tons—a 20-percent increase.

Table 34 compares the number of cleaning plants and the tons of cleaned coal, by types of equipment, for 1950 and 1951. During 1951, 608 wet-washing and 94 pneumatic cleaning plants were in operation. Seventy-one tipples used both wet and dry methods at the same plant; deducting these duplications gives a net total of 631 plants that cleaned coal in 1951, an increase of 19 plants over 1950.

Mines served by cleaning plants (exclusive of those that ship to washeries operated by steel companies) produced 302.3 million tons, or 57 percent of the total bituminous output in 1951. In this same group of mines, 232.4 million tons was cleaned mechanically; therefore, 77 percent of the coal produced at mines with cleaning plants in 1951 was cleaned at the mine. The remainder of the output from these piines (23 percent) presumably represents the larger sizes commonly mcked by hand. (*See* tables 36, 38, and 39.)

Relation Between Raw Coal, Clean Coal, and Refuse.—For every 100 tons of raw coal cleaned during 1951 at the mines, 83 tons of clean merchantable coal, on an average, was obtained, and 17 tons of refuse was discarded. Table 39 shows the total production of mines with cleaning plants and the results of cleaning operations, by States.

Methods of Mining at Mines Served by Cleaning Plants.—Underground mechanical loading appears to be closely related to mechanical cleaning. Underground coal loaded mechanically in 1951 totaled 304.3 million tons, of which 217.3 million tons (71 percent) passed through tipples equipped with mechanical cleaning devices. Production of coal from strip mines in 1951 was 117.6 million tons, of which 50.7 million tons (43 percent) came from strip mines having mechanical cleaning tipples. Hand-loaded underground coal production in 1951 totaled 111.8 million tons, of which 31 percent passed through tipples equipped with cleaning plants. (*See* tables 15 and 37.)

[1] In Alabama (for example) for every 100 tons of raw coal cleaned in 1951, an average of 27.6 tons of refuse was discarded and 72.4 tons of clean marketable coal was obtained.
[2] Includes some coal that was mined in Pennsylvania and cleaned in Ohio.
[3] Includes some coal that was mined in West Virginia and cleaned in Pennsylvania.
[4] Includes all mechanical cleaning other than washeries operated by consumer steel companies.
[5] Includes central washeries in Colorado and Pennsylvania operated by consumer steel companies.

BY STATES AND COUNTIES

Detailed production statistics are given in table 41 for each coal-producing county in the United States from which three or more operators submitted reports for 1951. Statistics on counties with less than three reporting producers have been combined with data for other counties in the same State to avoid disclosing individual figures, unless the operators have granted permission to publish them separately. Production of mines on the border between two States has been credited to the State from which the coal was extracted rather than to that in which the tipple was situated. If the coal is mined from lands in both States, the tonnage has been apportioned accordingly.

The data in this report, as in those published for many years by the Bureau of Mines, relate only to mines with an annual output of 1,000 tons or more. That fact should be borne in mind when the statistics in this report are compared with similar data compiled by State mine departments. Differences arise largely from variations in coverage by State reports, some of which include data for all mines regardless of size and others only data for mines employing more than a specified minimum number, ranging from 2 to 10 men.

Because of a change in the method of reporting, beginning with 1946, statistics of average production per man per day are not precisely comparable with those for other years. The figures since 1946 are based on the average number of men working daily, whereas the figures for previous years were based on the average number of men on the rolls per pay period

[1] Includes coal loaded at mine directly into railroad cars or river barges, hauled by truck to railroad siding, and hauled by truck to waterway.

[2] Includes coal used by mine employees, taken by locomotive tenders at tipple, used at mine for power and heat, transported to point of use by conveyor or tram, made into beehive coke at mine, and all other uses.

[3] Value received or charged for coal f. o. b. mine, including selling cost. (Includes a value for coal not sold but used by producer, such as mine fuel and coal coked as estimated by producer at average prices that might have been received if such coal had been sold commercially.)

[4] In certain counties the average tons per man per day is large due to strip mining or mechanical loading underground.

[1] Includes coal loaded at mine directly into railroad cars or river barges, hauled by truck to railroad siding, and hauled by truck to waterway.

[2] Includes coal used by mine employees, taken by locomotive tenders at tipple, used at mine for power and heat, transported to point of use by conveyor or tram, made into beehive coke at mine, and all other uses.

[3] Value received or charged for coal f. o. b. mine, including selling cost. (Includes a value for coal not sold but used by producer, such as mine fuel and coal coked as estimated by producer at average prices that might have been received if such coal had been sold commercially.)

[4] In certain counties the average tons per man per day is large due to strip mining or mechanical loading underground.

Shipped by truck from mine to final destination.		58,286,295	58,286,295	58,131,900	58,131,900
Used at mine [3]		13,216,720	13,216,720	15,161,518	15,161,518
Total production		516,311,053	516,311,053	533,664,732	533,664,732

[1] Includes coal loaded at mine directly into railroad cars or river barges, hauled by truck to railroad siding and hauled by truck to waterway. In general, figures show the quantity of bituminous coal and lignite originated for each railroad and waterway as reported by mine operators. It must be noted that in 1 year an operator may report coal loaded on the subsidiary railroad and in another year the same operator may report coal loaded on the parent railroad system.

[2] Includes coal shipped over Kanawha & Michigan, Kelley's Creek, Toledo & Ohio Central, and Zanesville & Western.

[3] Includes coal used by mine employees, taken by locomotive tenders at tipple, used at mine for power and heat, coal transported from mine to point of use by conveyor or tram, coal made into beehive coke at mine, and all other uses at mine.

STOCKS

Stocks of bituminous coal and lignite in the hands of industrial consumers and at retail yards in 1942–51 are shown graphically in figure 1. Stocks at upper Lake docks in 1950–51 are listed in table 1.

PRICES

The average values per ton of bituminous coal and lignite sold in 1900–1951 are listed in table 3, and those sold in 1905–51 are plotted in figure 2. The average values, classified according to method of mining, in 1925–51 are shown in table 20. The unit prices of railroad fuel and coking coal and the average retail price in 1950–51 are quoted in table 1. Figure 1 includes a graph of prices of railroad fuel in 1942–51. Lignite values are shown separately in tables 48 and 49.

LIGNITE [6]

The consumption of lignite in generating electric energy amounted to 1,520,616 net tons or 46 percent of total production in 1951, according to the Federal Power Commission. The principal consumption was in North Dakota, Minnesota, and South Dakota, with a very small amount in Colorado.

[6] Detailed data, by counties, shown in tables 40 and 41, and by size of mine in tables 11 and 12.

[1] Data cover period January through July; data not available for balance of year.

WORLD PRODUCTION

World production of anthracite and bituminous coal amounted to 1,591 million metric tons in 1951 and of lignite, 324 million tons—a total of 1,915 million tons. Total coal output in 1951, including lignite, exceeded that in 1950 by 110 million metric tons. Of the total world coal output, 72 percent was produced in four countries—the United States, Russia, Germany, and the United Kingdom. The United States supplied 523 million metric tons (bituminous, anthracite, and lignite) or 27 percent of the world output in 1951.

Most coal-producing countries in Europe increased production during 1951; however, consumption requirements of the principal coal-producing countries on the European Continent exceeded available supplies.

Although world production of anthracite, bituminous coal, and lignite increased in 1951, the European output was inadequate to meet requirements, and production from the United States made up a large part of the deficit.

Lignite (total of items shown above)	269,000	290,000	273,000	284,000	324,000
Bituminous coal and anthracite (by subtraction)	1,385,000	1,429,000	1,381,000	1,521,000	1,591,000

[1] This table includes a number of revisions of figures published in the 1950 Coal-Bituminous and Lignite chapter. Coal is also mined in British Borneo, Faroe Islands, and Italian East Africa (formerly), but production figures are not available and no estimate is included in the total.
[2] In addition, the following quantities (metric tons) of asphaltite were produced and used as solid fuels: 1947, 80,900; 1948, 82,289; 1949, 79,477; 1950, and 1951, data not available.
[3] Estimate.
[4] Data not available; estimate included in total.
[5] Does not include production of the Saar.
[6] Planned production.
[7] Norwegian mines only.
[8] Includes open-cast coal as follows, in thousands of tons: 1947, 10,410; 1948, 11,937; 1949, 12,639; 1950, 12,380; 1951, 11,148.
[9] Production less than 500 tons.
[10] Excludes production of Ombilin mines in Sumatra.
[11] Fiscal year ended Mar. 20 of year following that stated.
[12] Formerly Karafuto.
[13] Output from U. S. S. R. in Asia included with U. S. S. R. in Europe.

Coal—Pennsylvania Anthracite

By J. A. Corgan, Marian I. Cooke, and J. A. Vaughan

GENERAL SUMMARY

PENNSYLVANIA anthracite production in 1951 totaled approximately 42.7 million net tons.[1] The 1951 production figures include for the first time the output of independent operators who were formerly classified as "bootleggers." With inclusion of this tonnage (approximately 1.5 million tons), the 1951 output represents a 3-percent decline from 1950. This decline in production was due almost entirely to a decreased demand in the United States, which more than counterbalanced a substantial increase in exports. Exports to countries other than Canada increased from 93,000 tons in 1950 to 2,474,000 tons in 1951, while shipments to Canada were down about 300,000 tons. As anthracite is primarily a space-heating fuel, weather conditions are an important factor in consumption. Average 1951 temperatures in the principal anthracite markets were about the same as in 1950; therefore, a large part of the decline in the demand for anthracite in the United States was due undoubtedly to the inroads made into the anthracite markets by natural gas and heating oils.

According to data of the Pennsylvania Department of Mines, the New England and Middle Atlantic States received 80 percent of the total anthracite shipments during 1951, other States 6 percent; 9 percent was shipped to Canada and 5 percent to all other countries.

The percentages of anthracite produced by the various types of mining showed some changes from the 1950 pattern, as the proportion produced by culm-bank recovery increased while underground and strip-pit output declined. Underground operations supplied 62 percent of the 1951 total; strip pits, 26 percent; culm banks, 11 percent; and dredges, 1 percent. The average number of men working in the industry decreased 5 percent from the 1950 figure; but productivity increased slightly, principally as a result of the relative increase in culm-bank output. The decline in production resulted in short working time at many operations, hence the average number of days worked in the industry was also lower than in 1950.

Statistical Trends.—Summary data on the Pennsylvania anthracite industry are given in tables 1, 2, and 3.

Anthracite Committee.—The Anthracite Standards Law of the Commonwealth of Pennsylvania, as amended May 18, 1949, was amended further by the General Assembly of the Commonwealth of Pennsylvania by an act approved September 26, 1951, to implement the enforcement provisions of the law. Under this act of the assem-

[1] All tonnage figures in this chapter are expressed in net tons of 2,000 pounds unless otherwise stated.

Digitized by Google

bly, the quality of each shipment of anthracite leaving a breaker or preparation plant by rail or truck for points within or outside the State of Pennsylvania must be attested as "standard" or "substandard" by a responsible officer of the shipping company. Inspectors of the Anthracite Committee were engaged throughout the year in sampling and testing shipments of coal to ascertain whether the product being shipped met fully the quality requirements of the law. Specifications for "standard" anthracite, approved by the Anthracite Committee and incorporated into the original act of the Pennsylvania General Assembly dated May 31, 1947, are shown in table 4.

The committee also continued to administer the Production Control Plan to regulate production so as to reduce uneconomic mining and waste of valuable natural resources. During 1951 the committee extended its efforts toward eliminating the "bootlegging" of anthracite.

Anthracite Institute.—The Anthracite Institute continued its extensive advertising campaigns in newspapers and trade journals in 1951. These programs were designed not only to retain present consumers of anthracite but to expand the market by stressing its advantages to architects, combustion engineers, and property-management interests. A weekly ½-hour television show of the home-hobby type was presented during the latter half of the year; over 11 stations covered the primary anthracite market areas. A special exhibit, featuring all types of modern anthracite-burning equipment, was featured at 30 local farm and home shows in 7 States and Canada.

The 16 field representatives of the institute continued to act as instructors in schools for retail dealers and their employees and as consultants to owners and property-management executives on fuel problems. The field representatives also spoke on the use of anthracite before many private and public audiences and, in many instances, advised local authorities on the promulgation of effective antismoke ordinances. Institute representatives appeared as witnesses before congressional, Federal, and State bodies on matters of concern to the industry.

The institute laboratory continued work on basic research problems and in testing and developing anthracite equipment. Projects on mining and utilization were carried out in cooperation with Pennsylvania State College and the U. S. Bureau of Mines. (*See* Technology section of this chapter.)

Labor Relations.—There were no general work stoppages in the anthracite industry during 1951, as relations between management and labor continued to be amicable throughout the year. A new contract between the United Mine Workers of America and the anthracite operators became effective on February 1, 1951, without interruption of work. The new agreement continued the provisions of the contract of March 16, 1950, and granted a further wage increase of $1.60 per day to the miners. The new contract provided for termination by either party on 60 days written notice, but in no event before March 31, 1952.

Sources and Acknowledgments.—Basic statistics of the Pennsylvania anthracite-mining industry in this chapter are prepared from a mail canvass of all known anthracite operations; about 99 percent of the tonnage is reported in this manner, and the remaining 1 percent is estimated from collateral evidence. The data on individual operations furnished by the producers are voluntary and confidential, as is customary in the statistical services of the Bureau of Mines. In assembling available detailed information, free use has been made of the pertinent statistics prepared by the Pennsylvania Department of Mines, the Anthracite Institute, the Anthracite Committee, and the Association of American Railroads; thanks are extended to all of them for their cordial and continued cooperation.

TABLE 4.—Standard anthracite specifications approved and adopted by the Anthracite Committee effective July 28, 1947 [1]

	Round test mesh, inches	Percent					
		Oversize, maximum	Undersize [2]		Maximum impurities [3]		
			Maximum	Minimum	Slate [4]	Bone or ash [5]	
Broken	Through 4⅜				1½	2	11
	Over 3¼ to 3		15	7½			
Egg	Through 3¼ to 3	5			1½	2	11
	Over 2⁷⁄₁₆		15	7½			
Stove	Through 2⁷⁄₁₆	7½			2	3	11
	Over 1⅝		15	7½			
Chestnut	Through 1⅝	7½			3	4	11
	Over 1³⁄₁₆		15	7½			
Pea	Through 1³⁄₁₆	10			4	5	12
	Over ⁹⁄₁₆		15	7½			
Buckwheat No. 1	Through ⁹⁄₁₆	10					13
	Over ⁵⁄₁₆		15	7½			
Buckwheat No. 2 (Rice)	Through ⁵⁄₁₆	10					13
	Over ³⁄₁₆		17	7½			
Buckwheat No. 3 (Barley)	Through ³⁄₁₆	10					15
	Over ³⁄₃₂		20	10			
Buckwheat No. 4	Through ³⁄₃₂	20					15
	Over ³⁄₆₄		30	10			
Buckwheat No. 5	Through ³⁄₆₄	30	No limit				16

[1] A tolerance of 1 percent is allowed on the maximum percentage of undersize and the maximum percentage of ash content.
[2] The maximum percentage of undersize is applicable only to anthracite as it is produced at the preparation plant.
[3] When slate content in the sizes from Broken to Chestnut, inclusive, is less than these standards, bone content may be increased by 1½ times the decrease in the slate content under the allowable limits, but specified slate content shall not be exceeded in any event.
[4] "Slate" is defined as any material that has less than 40 percent fixed carbon.
[5] "Bone" is defined as any material that has 40 percent or more, but less than 75 percent fixed carbon. Ash determinations are on a dry basis.

PRODUCTION

The production of Pennsylvania anthracite totaled 42,669,997 tons in 1951. Included for the first time in 1951 are 1,544,076 tons prepared by independent operators. It was not considered advisable until 1951 (by which time illegal mining had been eliminated, largely by legal agreements made with the owners of the coal lands) to include the production of the independents owing to inadequate coverage. Information available on the activities of the independents, formerly called "bootleggers," who began operating during the depression years of the 1930's on lands neither owned nor leased by them, has been presented in previous chapters of the Minerals Yearbook. Inasmuch as the independent mining is centered in the Schuylkill region, inclusion of the independent tonnage will have no effect upon data for the Wyoming and Lehigh regions; however, such inclusion does preclude any direct comparison between total industry and Schuylkill region data for 1951 with that published for prior years. For example, if the independent tonnage were not included, the decrease between production in 1950 and 1951 would have been 7 percent rather than the 3 percent indicated by the totals shown for the two years. A small tonnage (28,762 tons) of Sullivan County semianthracite is also included in the 1951 output.

Grand total	57,190,009	57,139,948	42,701,724	44,076,703	42,669,997

[1] *See* footnote 1, table 1.
[2] For purposes of historical comparison and statistical convenience, the mines of Sullivan County are grouped with the Pennsylvania anthracite region, although the product is classified as semianthracite according to the American Society for Testing Materials Tentative Standard.
[3] Small quantity of washery coal included with "Breakers."

Breakers and Washeries.—Run-of-mine anthracite ranges in size from large lumps to the finest dust and contains such impurities as slate and rock. The exacting requirements of the market necessitate thorough cleaning of this material. The modern breaker is equipped with complete crushing and screening equipment for breaking down the larger masses of coal and for separating the crushed coal into the several sizes. By various means, such as washing, the use of jigs and tables, froth flotation, and heavy-medium separators, all foreign bodies are removed from the coal and the ash, slate, and bone content brought within the specification limits for "standard" anthracite.

Digitized by Google

The smaller sizes of anthracite have been used as fuel only since the turn of the century, as the equipment to burn them efficiently was not available. In the early years many millions of tons of the smaller particles of coal had been dumped with the mine and breaker refuse into large culm or refuse banks. With development of the necessary burning equipment, the use of the smaller sizes increased so rapidly that current production was insufficient to supply the demand. Washeries, or small preparation plants equipped with washing and screening facilities, were erected near the culm banks to recover the coal contained in them, thus depleting many of the banks of marketable coal. As little coal of the fine sizes currently produced is lost in the refuse, the culm banks will cease to be an important source of anthracite in the near future.

TABLE 6.—Pennsylvania anthracite shipped outside producing region, sold locally, and used as colliery fuel in 1951, by regions

Region and type of plant	Shipments outside region		Local sales		Colliery fuel		Total	
	Net tons	Value [1]	Net tons	Value	Net tons	Value	Net tons	Value [1]
Lehigh:

By Weeks and Months.—The weekly and monthly production figures for anthracite published in the Bureau of Mines Weekly Anthracite and Beehive Coke reports are estimated from records of railroad carloadings and from reports obtained from trade sources. The data so obtained have been adjusted in tables 13 and 14 to the total annual anthracite production as obtained by a direct mail canvass of the operators.

TABLE 13.—Estimated weekly production of Pennsylvania anthracite in 1951 [1]

Week ended—	Thousand net tons	Week ended—	Thousand net tons	Week ended—	Thousand net tons	Week ended—	Thousand net tons

[1] Estimated from weekly carloadings as reported by the Association of American Railroads. *See* table 13.
[2] *See* footnote 1, table 1.

Culm-Bank Coal.—The recovery of anthracite from culm banks in 1951 was 34 percent greater than in 1950 and was 11 percent of total production from all sources. It is believed that the increase was due to a renewed demand in Europe for the smaller sizes, as considerable quantities of Buckwheat No. 2 and smaller were shipped abroad during the year. Tables 15 and 16 give details on production, by regions and fields.

[2] A small quantity of culm-bank coal was put through breakers in Sullivan County.

MINING METHODS AND EQUIPMENT

Mechanical Loading.—Of the total underground production of Pennsylvania anthracite in 1951, 41 percent was loaded mechanically compared with 44 percent in 1950. The tonnage loaded mechanically in 1951 was 12 percent less than in 1950. The coal seams of the Northern field are relatively flat when compared with the more sharply pitching beds of the other fields and are thus more adaptable to machine loading—hence, 86 percent of the total loaded mechanically in 1951 was produced in the Northern field compared with 14 percent for the 3 others combined. Data on mechanical loading underground are presented in tables 17 to 19. Trends in the mechanical loading, hand loading, and stripping of Pennsylvania anthracite, 1928–51, are shown in figure 1.

[1] *See* footnote 1, table 1.
[2] As reported by Pennsylvania Department of Mines.

Cutting Machines.—The tonnage of anthracite cut by machines declined 19 percent from 1950. All 152 machines used in 1951 were of the "permissible" type.

Strip-Pit Operations.—Anthracite produced by strip-pit operations was 30 percent of the total fresh-mined output in 1951, the same as for the preceding year. Of the total strip-pit production, 58 percent was obtained in the Schuylkill region, 24 percent in the Wyoming region, and 18 percent in the Lehigh. The relatively high rate of production in the Schuylkill region is due to the outcropping of many thick, highly pitched seams. (Data on strip-pit operations are shown in tables 20 and 21.) Figure 2 shows graphically the growth of strip-pit production during the period 1928–51.

Dredge Coal.—Production of Pennsylvania anthracite by dredges operating in the Lehigh, Schuylkill, and Susquehanna Rivers and their tributaries in 1951 declined 9 percent from 1950. The total represented the lowest annual output since 1936. It is expected that production of river coal will continue to decline as reserves of this fuel become less. Pennsylvania laws prohibit the drainage of untreated mine or breaker water into the surface streams, thus preventing any large deposition of coal on the river and creek beds. Electric power and other industrial plants located in or near the anthracite fields, formerly dependent upon dredge operators for a substantial part of their fuel requirements, undoubtedly will obtain more of their future needs from the preparation plants recovering the finer particles of coal by froth flotation, settling ponds, etc.

EMPLOYMENT

The average number of men working in the Pennsylvania anthracite industry during 1951 totaled 68,995. Of the total labor force, 66 percent were engaged underground, 11 percent in strip pits, and the remaining 23 percent in preparation plants and other surface occupations. By regions, the total number of men working was divided as follows: 51 percent in the Wyoming region, 33 percent in the

Schuylkill, and 16 percent in the Lehigh. The 1951 data include workers employed by the independent operators, formerly categorized as "bootleggers." These operations are now being conducted largely under leasing arrangements with the landowners. As pointed out in the discussion of production, the addition of these workers has the most drastic effect upon the comparability of 1951 data for the Schuylkill region with that for earlier years, as the illegal mining was confined to that area. The addition of these workers also, of course, affects the employment totals of the industry.

Detailed labor statistics are shown in tables 24 and 25.

TABLE 25.—Average number of men working at operations producing Pennsylvania anthracite, 1950–51, by counties

[Includes operations of strip contractors]

County	1950	1951 [1]	County	1950	1951 [1]

[2] None in Wayne in 1950.
[3] Counties producing dredge coal only.

CONSUMPTION

Although production of Pennsylvania anthracite declined only 3 percent in 1951 including the tonnage produced by independents, apparent consumption (calculated on the basis of production, imports, exports, and changes in producers' stocks) in the United States declined 7 percent owing to a sharp decrease in the space-heating market.

The tonnage of anthracite fines mixed with bituminous coal in the manufacture of coke increased from 169,275 tons in 1950 to 237,136 tons in 1951. Reported consumption at electric-power plants increased 7 percent—from 3,608,863 tons in 1950 to 3,869,512 in 1951. The consumption of anthracite in the manufacture of briquets declined 20 percent from the 638,356 tons used in 1950, as production in that industry decreased. The quantity used by railroads also dropped—from 771,888 tons in 1950 to 678,229 tons in 1951.

According to the Pennsylvania Department of Mines, anthracite shipments to the primary anthracite market area (New England and Middle Atlantic States, Maryland, Delaware, and District of Columbia) comprised 96 percent of the total shipments to destinations in the United States, the same percentage as in 1950. Data on the consumption of all fuels in this area are not available; however, the apparent consumption of anthracite, domestic coke, briquets, and heating and range oils, in terms of anthracite, are shown in table 26.

Mechanical Stokers.—According to data of the Bureau of the Census, United States Department of Commerce, factory sales of class 1 stokers (burning capacity, under 61 pounds of coal per hour) increased from 4,191 in 1950 to 4,268 in 1951. Sales of class 2 stokers, with a

[1] Pennsylvania Department of Mines; illicit coal not included.
[2] An important but undetermined part of anthracite shown as shipped to New Jersey is reshipped to New York City.
[3] U. S. Department of Commerce.
[4] Less than 0.05 percent.
[5] Less than 500 tons.
[6] Converted to coal equivalent upon basis of 4 barrels of fuel oil equaling 1 ton of coal.

burning range between 61 and 100 pounds of coal per hour, declined 15 percent to 414 units (487 units in 1950).

DISTRIBUTION

Data on the distribution of Pennsylvania anthracite in table 27 are based on reports submitted voluntarily to the Bureau of Mines by producers, American and Canadian wholesalers, and dock operators. As these data cover the coal year ended March 31, 1951 they are not comparable with other 1951 data in this chapter which cover the calendar year.

Shipments reported to the Bureau of Mines for the 1950–51 coal year totaled 41.9 million net tons or slightly less than 1 percent over the 1949–50 total.

Digitized by Google

Various reasons, such as competition from natural gas and heating oils, have been given for the decline in anthracite production since the 1947–48 coal year, but another significant factor was that the winter of 1950–51 marked the third successive heating season in which average temperatures in the primary anthracite markets ranged substantially higher than normal. In spite of weather conditions unfavorable from the standpoint of anthracite consumption, shipments to points in the United States were approximately 2 percent higher than in the 1949–50 coal year and about 5 percent greater in Canada. Exports to Ontario were approximately 9 percent higher, but shipments to Quebec and the Maritime Provinces declined 8 and 17 percent, respectively. The most significant change in distribution occurred in shipments to countries other than Canada, as only 263,901 net tons were exported during the 1950–51 coal year compared with 1,040,315 tons during the 1949–50 coal year. However, monthly export data of the Bureau of the Census, United States Department of Commerce, indicate that the volume exported to non-Canadian destinations will exceed 2.8 million tons for the 1951–52 coal year.

According to monthly reports of the Pennsylvania Department of Mines, 35.3 million net tons of anthracite was shipped from mines in the calendar year 1951. Of this total, 6.3 million tons, or 18 percent, was shipped by truck and the remainder by rail; an undetermined part of the rail tonnage, however, subsequently reached final destinations by tidewater or lake carriers. In 1951 about 55 percent of the truck movement, as compared to 54 percent in 1950, was destined within the producing region and 45 percent (46 percent in 1950), to points outside the region. Data compiled by the Interstate Commerce Commission indicate that Pennsylvania anthracite ranked second in 1951 in carload originations and tonnage on the 49 class I railroads comprising the Eastern district. Nine of these railroads originated all of the anthracite produced. Anthracite rail shipments, by State of destination, are shown in table 28, and truck shipments, by month and State of destination, in table 29.

Data compiled from records of the Massachusetts Division on the Necessaries of Life and the Association of American Railroads show that New England rail receipts of Pennsylvania anthracite in 1951 decreased 13 percent from 1950 while tidewater receipts declined 38 percent. Details on anthracite movement to New England are shown in table 30.

[1] 1941 and earlier years from Commonwealth of Massachusetts, Division on the Necessaries of Life; data for 1942 and succeeding years, as reported by Association of American Railroads.
[2] Commonwealth of Massachusetts, Division on the Necessaries of Life.
[3] U. S. Department of Commerce.
[4] Total receipts by rail and by tidewater less imports.
[5] Less than 500 tons.

There was a substantial reduction in the Lake movement of anthracite in 1951, as loadings at Lake Erie ports dropped almost 25 percent from the 1950 volume of 611,409 tons. Loadings at Lake Ontario ports totaled 58,228 tons, down 65 percent from 1950, while receipts at upper Lake docks totaled 503,455 tons in 1951, a decline of 27 percent.

Shipments of anthracite from the Lehigh, Schuylkill, and Wyoming regions, 1890–1951, are shown graphically in figure 3.

STOCKS

Producer's stocks of Pennsylvania anthracite at the end of December 1951 totaled 982,396 tons compared with 1,268,300 tons in December 1950, a decrease of approximately 23 percent. Stocks on the upper Lake docks were also down, falling from 242,237 tons at the end of December 1950 to 197,790 tons in December 1951; the low point for the year was reached in March, when only 92,958 tons was in stock on the upper Lake docks. Anthracite stocks at electric utility plants at the close of 1951 were approximately 9 percent higher than in December 1950 and during the latter months of the year exceeded 5 million tons. Stocks of class I railroads again declined, totaling 49,097 tons at the end of December 1951 compared to 61,081 tons in 1950.

Stocks of anthracite in retail dealers' yards on December 31, 1950 were estimated by the Bureau of Mines at 3,452,000 tons, comprised of 2,041,000 tons of Egg, Stove, and Chestnut sizes, 342,000 tons of Pea, and 1,069,000 tons of Buckwheat No. 1 and Buckwheat No. 2. Stocks on December 31, 1951, were estimated as follows: Egg, Stove, and Chestnut sizes, 1,552,000 tons; Pea, 283,000 tons; and Buckwheat No. 1 and No. 2 sizes, 859,000 tons.

PRICES

Pursuant to the Defense Production Act of 1950, the Office of Price Stabilization placed ceiling prices on Pennsylvania anthracite at the mine or preparation plant by the issuance of Ceiling Price Regulation 4, effective February 1, 1951. As the producers had incurred higher costs after the outbreak of the conflict in Korea in 1950 owing to increases in miners' wages and taxes the ceiling prices set generally reflected these higher costs. Under CPR–4, the practice of making service charges for split cars, oil and calcium chloride treatment, pocket loading of trucks, etc., was continued. In addition, those companies that had in the past sold coal from certain seams or preparation plants at a premium (usually $0.25 per ton) were permitted to add the extra charge to the established ceilings.

The entire ceiling price structure was based upon the specifications for "standard" anthracite, as approved by the Anthracite Committee (see table 4), and specified the amounts by which the ceiling prices had to be lowered for substandard coal. Ceiling prices for standard anthracite were as follows: Broken, $14.20 per net ton; Egg, $14.45; Stove, $14.70; Chestnut, $14.60; Pea, $11.40; Buckwheat No. 1, $8.00; Buckwheat No. 2 (Rice), $6.40; Buckwheat No. 3 (Barley), $5.10; and Buckwheat No. 4 and smaller, $4.10. Prices on coal not meeting the specifications for standard anthracite were $1.15 less per ton for Broken through Chestnut sizes; $1.00 for Pea; $0.70 for Buckwheat No. 1; $0.60 for Buckwheat No. 2 (Rice); $0.50 for Buckwheat No. 3 (Barley); and $0.40 for Buckwheat No. 4 and smaller. According to Saward's Journal, prices being quoted in December 1951 were either the ceiling prices shown above, or $0.25 per ton higher for the premium coals. Data compiled from reports of the Bureau of Labor Statistics, United States Department of Labor, on retail prices of certain fuels in selected cities for 1951, by months, are shown in table 31.

Grand total	9.12	8.28	3.66	8.90	9.70	9.10	4.36	9.51

[1] Value given for shipments is value at which coal left possession of producing company and does not include margins of separately incorporated sales companies.
[2] *See* footnote 1, table 1.

FOREIGN TRADE [2]

Exports of Pennsylvania anthracite to all countries totaled 6 million net tons in 1951, a 53-percent increase over 1950. Although shipments to Canada declined 8 percent from the 1950 total, exports to the rest of the Western Hemisphere and to Europe increased substantially. The tonnage exported in 1951 represented the fifth largest annual total recorded in the history of the industry.

In the latter half of 1950, it became apparent that, even though western European coal production had shown progressive improvement since the close of World War II and had almost reached the 1938 level, requirements could not be met adequately without the importation of large quantities of American coal. As a result, shipments of anthracite to Europe in 1951 totaled 2.4 million tons. Monthly data of the Bureau of the Census, United States Department of Commerce, show that the revival of the trade with Europe began in December 1950, as 50,059 tons of the 1950 total of 81,930 tons was shipped in that month alone; exports to Europe for the first quarter of 1951 totaled 147,008 tons; the second quarter, 352,960; the third quarter, 894,221; and the fourth quarter of the year, 1,032,458. It is estimated that approximately 46 percent of the total exported to Europe in 1951 consisted of Pea and larger sizes and the remainder Buckwheat No. 2 and smaller. Export data are shown in detail in table 35.

The decline in shipments to Canada from 3.8 million tons in 1950 to 3.5 million in 1951 may be attributed to the continuation of mild weather conditions, with temperatures averaging well above normal in the eastern part of that country, as over 95 percent of the anthracite shipped to Canada in recent years has been space-heating sizes (Buckwheat No. 2 and larger). Competition from Welsh anthracite declined during the year, as shipments to Canada from Great Britain fell from 395,865 tons in 1950 to 291,655 in 1951.

Imports of anthracite for consumption in the United States totaled 26,812 net tons in 1951; all came from Great Britain. Details on imports are presented in table 36.

TECHNOLOGY

The Bureau of Mines anthracite research laboratory at Schuylkill Haven, Pa., was virtually completed in 1951. It was expected that research on problems relating to the mining, preparation, and utilization of anthracite would be accelerated as rapidly as available funds permitted, with completion of the laboratory and formation of the various advisory committees. For several years before erection of the laboratory, Bureau personnel stationed in the anthracite region cooperated closely with the industry and the Anthracite Institute in practical research work. Research begun in 1944 was continued on scraper-shaker loading machines for driving gangways, and tests were run with the Eickhoff shearing machine, model DEK, to obtain data on power requirements for cutting anthracite. The Korfmann universal shearing machine, model SK–20, was tested to determine its power characteristics, maneuverability, and general qualities in cutting anthracite. Experiments were also made on pneumatic packing with a Brieden machine. Much of this research has been discussed previously in Minerals Yearbook chapters on Pennsylvania anthracite, and various publications related to this work are cited in those chapters. Formal establishment of the industry groups advisory to the laboratory was expected to be of valuable assistance in selecting and completing projects. Mining projects underway in 1951 or planned for early 1952 related to: Loads borne by roadway supports (the objective of this study was to obtain data on loads borne by mine timber as a basis for designing a steel protection shield to eliminate the installation of timber by face miners); a mechanical method for mining coal left below rock holes in thick, steeply pitching anthracite beds; compressed-air transmission, distribution, and storage underground in anthracite mines; the use of yielding steel supports (Becorit props) in mining thick, flat seams; continuation of practical research in back filling with Brieden pneumatic packing machines; continuation of experimental work with the Bureau of Mines scraper-shaker loading machine; mining of steeply pitching anthracite beds by induced block caving; and the use of lightweight concrete roof supports.

In anthracite utilization, the Bureau worked principally on the operation and performance of small commercial and industrial anthracite-burning equipment. This was a continuing project conducted in the anthracite research laboratory heating plant and boiler room. Research also was continued cooperatively with private industry on investigations in atmospheric fixed-bed-type anthracite gas producers. Information obtained from the gas-producer tests would supplement information already obtained on this subject from cooperative work conducted for a number of years by the Anthracite Institute, the Commonwealth of Pennsylvania, and Pennsylvania State College. Cooperation was given to the Anthracite Institute and private industry on projects and tests related to the feasibility of making from bone coal a producer gas for underfiring colliery boilers.

In coal preparation the Technical Advisory Preparation Subcommittee recommended that launder-screen investigations be continued, that studies on dewatering and drying fine coal be inaugurated, and that work begin on grinding anthracite to obtain the necessary data for determining the merits of hammer-mill and roll crushing in preparing anthracite. The subcommittee also suggested that a study

Digitized by Google

be made of the removal of cinders from anthracite, as this problem is important in preparing anthracite recovered by strip-mining and spoil-bank operations.

The Bureau of Mines has done considerable investigation of the anthracite mine-water problem, most of which has been discussed briefly in previous anthracite chapters of Minerals Yearbooks. Mine water from anthracite workings is generally pumped, drained away by gravity, or stored underground in huge quantities. The drainage systems in the anthracite region handle over 200 billion gallons of water annually; of this, more than 150 billion gallons is pumped to the surface. Much of this water is used in the breakers in preparing coal, for allaying mine dust, in hydraulic back-filling, and for combating fires, etc.

To obtain a sound foundation upon which engineering studies of the mine-water problem could be based, it was first necessary to gather reliable data on all factors involved, such as the quantity of water impounded in abandoned and active mines, the volume of water being pumped from each mine, the condition of barrier pillars in abandoned mines or serving as protection for active workings, the extent and depth of the glacial deposits overlying the coal measures in the Northern field, the characteristics of water, and the effect of mine water upon surface streams. Many of the data required have been obtained by the Safety Branch of the Health and Safety Division of the Bureau of Mines, and the Bureau is continuing its engineering survey.

It has been suggested that the long-range solution of the anthracite mine-water problem might best be accomplished by a gravity tunnel system and several pumping plants. The proposal envisages a tunnel 80 miles in length and 16 feet in diameter, lined with concrete. Construction would be on a grade of 1 foot per mile, starting at a point on the Susquehanna River near Conowingo, Md., and extending to Mahanoy City, Pa., with laterals draining water from the Southern and Western Middle fields. From Mahanoy City to Glen Lyon—a distance of 23 miles—the tunnel would have a diameter of 14 feet. From Glen Lyon the tunnel would extend along the Northern field 38 miles to Scranton; this segment of the tunnel would start with a diameter of 13 feet and progressively decrease in size to 9 feet at its end. A survey was run along the proposed Conowingo-Glen Lyon tunnel system to locate possible shaft sites, and diamond-drill holes were put down at 15 places to determine the character of the underlying rock.[3] Information obtained from this drilling and other data pertaining to the proposed tunnel are published in Bureau of Mines Bulletin 513.

Work at the Anthracite Institute's laboratory at Wilkes-Barre, Pa., during 1951 was divided into basic research, development of equipment, and testing of equipment. In addition to its own research, the institute cooperated on technical projects with Pennsylvania State College, the Bureau of Mines laboratory at Schuylkill Haven, and various research groups of the bituminous-coal and coke industries.

Digitized by Google

Basic studies were begun during the year on the use of anthracite as a filtering aid by the chemical industry. Plant-scale tests using Chestnut-size bone coal in the Wellman-Galusha gas producer were conducted in cooperation with the Wellman Engineering Co. and the Bureau of Mines. The institute continued to investigate the possibility of promoting the use of anthracite in the drying of farm products. A low-cost tobacco-curing furnace was developed in the laboratories and received its first trial during the past curing season in Ontario, Canada, and in North Carolina. In its investigations of the development of equipment, the institute's laboratory conducted considerable research on commercial crossfeed stokers, and a new-type furnace for heating small, prefabricated homes was designed and built.

WORLD PRODUCTION

World production of anthracite in 1951 increased 4 percent over the 1950 output. Slight increases occurred in virtually all producing countries except the United States, North Korea, and Portugal. World production data for 1946–51 are presented in table 37.

Cobalt

By Hubert W. Davis and Charlotte R. Buck

GENERAL SUMMARY

COBALT consumption in the United States in 1951 reached the record total of 9,933,000 pounds, a 20-percent gain over 1950, itself a record year. Consumption of cobalt for high-temperature alloys, alloy hard-facing rods, and cemented carbides more than doubled in 1951, and substantially more cobalt was used in high-speed steel. These gains, however, were partly offset by substantial losses in consumption of cobalt in magnets, ground-coat frit, pigments, and low-cobalt alloy steels. Consumption of cobalt metal in 1951 was 24 percent greater than in 1950, but seven times more purchased cobalt scrap was used. These gains were balanced to some extent by reduced consumption of cobalt oxide, salts, and driers. So great was the demand for cobalt that, effective February 1, 1951, it was put under complete allocation by the National Production Authority, which also prohibited its use in manufacturing less essential products or in products in which substitute materials might be used effectively.

Cobalt-metal production in the United States in 1951 was 8 percent over 1950; but imports, which established a new record, were 21 percent larger. Sales of cobalt metal in the United States, however, were virtually the same in 1951 as in 1950; those to industry gained 22 percent, but deliveries to the National Stockpile were 38 percent smaller.

The demand for cobalt oxide declined substantially in 1951, chiefly because of the limitations on use in ground-coat frit for porcelain enamel and in pigments. The output of oxide in the United States exceeded that in 1950 by 23 percent, but imports were 52 percent less; sales declined 27 percent. Production and shipments of hydrate, salts, and driers were substantially smaller than in 1950.

A large part of the cobalt metal, oxide, hydrate, and other cobalt products sold in the United States is made from crude cobalt (white alloy) produced in Belgian Congo. Imports of white alloy from Belgian Congo exceeded those in 1950 by 6 percent. Belgian Congo also supplied a substantial quantity of cobalt granules, which are produced from precipitates recovered from the solutions used in electrolytic copper plants. Some cobalt products sold are made from domestic, Moroccan, and Canadian ores. The output of domestic ore was 12 percent greater than in 1950, and imports of Canadian ore were up 94 percent. Consumption of cobalt white alloy and ore increased 13 percent.

The prices of cobalt metal and oxide were advanced 60 and 38 cents a pound, respectively, during 1951.

Digitized by Google

Allocation of cobalt to the free-world countries for the fourth quarter of 1951 was announced on October 11 by the International Materials Conference. The United States was allocated 1,212 metric tons or 59 percent of the total.

A report on the utilization of cobalt and other metals was issued by the Joint Subcommittee of the International Materials Conference.[1]

Government Regulations.—An amendment of December 30, 1950, to National Production Authority Order M–10 in effect constituted a completely new order, inasmuch as the former Order M–10 contained only inventory-control provisions. In addition to carrying these on in similar form, amended Order M–10, effective January 31, 1951, prohibited the use of cobalt in manufacturing specified products that are relatively less essential or in which substitute materials might be effectively used; established limits on additions to inventory; and placed cobalt under allocation by prohibiting, subject to limited exceptions, deliveries not covered by allocation authorizations to be issued monthly by the National Production Authority.

The Office of Price Administration, under General Overriding Regulation 9, Amendment 4, exempted from price control cobalt ore and cobalt metal, effective August 10, and under General Overriding Regulation, Amendment 9, exempted cobalt oxide, effective October 12.

DOMESTIC PRODUCTION

Mine Production.—Despite the fact that the United States is the largest consumer of cobalt in the world, only a small part of its requirements have been furnished by domestic ore. (Table 1 shows domestic production and shipments through 1951.) However, there was a prospect of decreased dependence on foreign sources by 1954, when full production will have been attained by Calera Mining Co. in Idaho and Cobalt-Nickel Reduction Co. in Missouri.

Production and shipments of cobalt ore in the United States in 1951 were 12 and 14 percent, respectively, greater than in 1950.

The Bethlehem Steel Co. was the chief producer of commercial cobalt ore in the United States in 1951. The cobalt-bearing material (averaging 1.42 percent cobalt in 1951) is obtained as a flotation sulfide concentrate from the magnetite mined at Cornwall, Pa. The cobalt-bearing material is shipped to the Pyrites Co., Wilmington, Del., where it is processed into metal and other cobalt products.

The Sullivan Mining Co., Kellogg, Idaho, continued to recover cobalt at its electrolytic zinc plant in 1951 but, as in previous years, made no shipments. In 1951 it recovered 107 short tons of residues containing 7,885 pounds of cobalt.

The St. Louis Smelting & Refining Division of National Lead Co. continued to produce an iron concentrate carrying cobalt, nickel, and copper at its property near Fredericktown, Madison County, Mo. The cobalt content of reject concentrate produced in 1951 was 3.75 percent. Construction of a 50–ton plant (head feed) to process this is planned to begin early in 1952. The plant will be operated by Cobalt-Nickel Reduction Co. and is expected to produce cobalt,

[1] International Materials Conference, Utilization of Manganese, Nickel, Cobalt, Tungsten, Molybdenum. Washington, December 1951, 94 pp.

Digitized by Google

nickel, and copper at an annual rate of 1,386,000, 1,852,000, and 1,418,000 pounds, respectively.

TABLE 1.—Cobalt ore produced and shipped in the United States through 1951

Total	(1)	8,870,322	(1)	8,501,052

[1] Data not available.

The Calera Mining Co., a wholly owned subsidiary of the Howe Sound Co., began production of cobalt concentrates in June 1951 at its Blackbird mine at Cobalt, Idaho. The ore carries about 0.6 to 0.8 percent cobalt, about twice as much copper, and a little gold. The concentrates produced averaged 11.26 percent cobalt in 1951. According to the Howe Sound Co.: [2]

The concentrator at the mine, as originally designed for treating 600 tons of ore daily, was complete and ready for operation on July 1. The enlarged plant with a capacity of 1,000 tons per day is nearing completion at this writing (Feb. 29, 1952).

Completion of the refinery near Garfield, Utah, has not been possible because of frustrating delays in obtaining delivery of equipment and special supplies. * * * Construction of the plant has continued with a small crew and as equipment has been received it has been installed, or preparations have been made for quick installation when a larger crew is available. Barring the unforeseen breaking down of delivery schedules it is now expected that the plant will be ready for operation by the end of June.

No attempt was made during this time to block out additional ore and the small underground crew was utilized in preparing stopes for production so that, upon completion of the refinery, capacity operation could be developed as rapidly as the labor force could be expanded. The ore extracted from this preparatory work was milled with the concentrator operating one shift per day at partial capacity. Resulting copper concentrate was sold as produced and the cobalt concentrate was stored. This arrangement allowed for a thorough preliminary testing of the new flotation process which has been developed in the research laboratories of the Company. Difficulties encountered were rectified and necessary changes in the flow sheet were made and it is now expected that results which will be obtained under full operating conditions will be at least as good as those indicated by small scale tests made in the laboratory and pilot plant.

The construction of additional apartments and dormitories was continued and is approaching completion. During the year the road between the mine and the main highway near Challis, Idaho, a distance of over 40 miles was improved by the Government and after surfacing is completed, early in 1952, it will be a reasonably good all weather highway.

This concentrator was described more fully in a trade journal article.[3]

Refinery Production.—Consumption by refiners or processors of cobalt contained in alloy and ore was 2,857,328 pounds in 1951—a 13-percent increase over 1950. However, consumption of cobalt intermediates by refiners or processors was 25 percent less. Of the alloy and ore consumed in 1951, much the greater part was utilized in making cobalt metal.

TABLE 2.—Cobalt products produced and shipped in the United States, 1950–51, in pounds

Other				17,565	48,261	**48,549**

[1] Total consumption is not shown, since the fines, granules, rondelles, hydrate, and carbonate originated from alloy and ore; combining alloy and ore with these materials would result in duplication.

CONSUMPTION

Industrial consumers established a new record in 1951, using 9,932,993 pounds, a 20-percent gain over 1950, the previous record

[3] Mining World, Sweat, Ingenuity, Dollars; A New Mine for Howe Sound: Vol. 13, No. 12, November 1951, pp. 40–43.

Digitized by Google

year. The largest single use for cobalt in 1951 was for cobalt-chromium-tungsten-molybdenum alloys, which represented 49 percent of the total quantity consumed and utilized 120 percent more than in 1950.

Magnet alloys, the largest utilizer of cobalt since 1946, dropped to second place in 1951 and used only 21 percent of the total consumed; moreover, consumption for this purpose was 26 percent less than in 1950. A cobalt-platinum magnet, which, in small sizes, is described as the world's most powerful permanent magnet, has been developed by scientists of the General Electric Research Laboratory.[4]

Less cobalt was also used in low-cobalt alloy steels, ground-coat frit for porcelain enamel, and pigments. These losses, however, were largely offset by greater use of cobalt in high-speed steel, alloy hard-facing rods, and cemented carbides. Cobalt salts and driers were utilized at a rate about 26 percent less than in 1950.

Grand total	4,154,722	5,019,224	4,701,926	8,283,408	9,932,993

An analysis of the function of cobalt oxide in promoting adherence to sheet-iron ground-coat enamels [5] and a study of the possibility of using other materials to accomplish the same result [6] have been made. A patent has been issued for "cobalt-base, cast alloys containing carbon, chromium and metal of the group tungsten and molybdenum as essential constituents, and such as are primarily adapted for cutting tools, particularly of the high-speed variety, and which are also adapted for other wear- and abrasion-resisting applications, for example, dies." [7]

The use of cobalt isotope for steel inspection was reported.[8] Success-

ful application of cobalt-60 as a source of gamma rays for industrial radiography was also announced.[9]

TABLE 5.—Cobalt consumed in the United States, 1947–51, by form in which used, in pounds of contained cobalt

PRICES

The price of cobalt metal (97–99 percent, in 500–600-pound kegs) was increased to $2.10 a pound f. o. b. Niagara Falls or New York, N. Y., on January 1, 1951, and to $2.40 a pound on October 1. The former price of $1.80 a pound had been in effect since April 1, 1949. On January 1 the price of ceramic-grade oxide was advanced to $1.60 a pound (gross weight) east of the Mississippi River, and on November 8 it was raised to $1.76 a pound. The former price of $1.38 a pound had also been in effect since April 1, 1949. Sales of cobalt metal and ores were exempted from price control on August 10 and sales of oxide on October 12.

FOREIGN TRADE[10]

Imports.—Imports of cobalt into the United States established a new high of 10,338,000 pounds (cobalt content) in 1951 and were 14 percent larger than in 1950, the previous record year. Belgian Congo continued to be the chief source, in 1951 supplying 4,929,512 pounds of metal and 4,083,541 pounds of white alloy containing 1,904,429 pounds of cobalt. Belgium provided 3,000,500 pounds of metal and 431,767 pounds of oxide containing 306,400 pounds of cobalt; both metal and oxide were produced from Belgian Congo alloy. Canada furnished 182,700 pounds of metal, 4,750 pounds (gross weight) of oxide, 2,237 pounds (gross weight) of salts and compounds, and 344,872 pounds of ore containing 36,478 pounds of cobalt. Mexico contributed 146 pounds (gross weight) of zaffer and 192,291 pounds of ore containing 3,825 pounds of cobalt. France supplied 6,613 pounds of metal, the United Kingdom 1 pound of metal and 360 pounds (gross weight) of salts and compounds, and Germany and Switzerland 13 and 547 pounds (gross weight), respectively, of salts and compounds.

[1] Reported by importer to Bureau of Mines; not separately classified by U. S. Department of Commerce. Value not available.
[2] Includes 146 pounds of zaffer, valued at $215.
[3] Adjusted by Bureau of Mines.

During the 29 years 1923–51 receipts of metal comprised about 50 percent of the cobalt imports, most of which were supplied by Belgium and Belgian Congo. Smaller quantities of metal have been received from Austria, Canada, Finland, France, Germany, Japan, Sweden, and United Kingdom. Imports of alloy represented the second-largest quantity (36 percent); virtually all were from Belgian Congo. About 10 percent of the imports of cobalt have been in the form of oxide, chiefly from Belgium. Substantial quantities of oxide have also been received from Australia, Finland, and France. Cobalt ore has comprised about 4 percent of total imports; Canada has been the largest source, with most of the remainder coming from Australia and French Morocco.

Exports.—Exports of cobalt from the United States are small; 10,275 pounds of metal, alloys, and cobalt-bearing scrap valued at $63,968 was exported in 1951. Some oxide, salts, and driers are also exported, but the figures are not separately recorded by the United States Department of Commerce.

Tariff.—The duty on cobalt oxide continued to be 10 cents a pound, sulfate 5 cents a pound, and linoleate 10 cents until June 7, 1951, when it was reduced 50 percent under the Torquay Agreement. The duty on salts and compounds continued at 30 percent ad valorem. Cobalt metal and ore entered the United States duty-free.

WORLD REVIEW

Virtually all cobalt occurs in combination with other metals, such as copper, nickel, iron, arsenic, lead, zinc, manganese, silver, and gold. Belgian Congo and Northern Rhodesia, where cobalt is associated with copper, have been the chief producing countries in recent years, followed by the United States, Canada, and French Morocco. These five countries have been supplying about 95 percent of the world output of cobalt. Iron pyrites from Finland, Germany, Greece, Italy, Norway, Spain, and Sweden contains cobalt, of which some is recovered. Although the quantities of cobalt in iron pyrites are generally very small—often only 0.05 percent—and its recovery only 50 to 60 percent, the very large tonnage treated before and during the war contributed greatly to the cobalt production in Germany. It is reported [11] that about 10 tons of cobalt concentrates is obtained from 100,000 tons of cinder. A complete record of cobalt output from iron pyrites is lacking.

TABLE 7.—World mine production of cobalt, 1942–51, by countries, in metric tons of contained cobalt [1]

[Compiled by Berenice B. Mitchell]

Country [1]	1942	1943	1944	1945	1946	1947	1948	1949	1950	1951

[1] In addition to countries listed, Brazil, China, Germany, and Spain produce cobalt, but production data are not available. Estimate by author of chapter included in total.
[2] Data not available; estimate by author of chapter included in total.
[3] Less than 0.5 ton.
[4] Figures comprise Canadian ore processed in Canada and exported (irrespective of year when mined), plus cobalt content of concentrates made at Port Colborné from copper-nickel ore. However, figures exclude the cobalt recovered at Clydach, Wales, from Canadian nickel-copper ores, for which estimate by author of chapter has been included in world total.
[5] Revised figure.
[6] Year ended June 30 of year stated.

Belgian Congo.—The leading source of cobalt continues to be Belgian Congo; the Union Minière du Haut-Katanga, the only producer, reported an output of 5,875 metric tons in 1951, a new record. Production of cobalt in Belgian Congo was begun in 1924 and since that year has increased, almost without interruption; the total through 1951 is about 48,000 metric tons.

Union Minière has six 720-kw. electric furnaces at Jadotville and one of 2,000 kw. for smelting cobalt ores and concentrates from the Kolwezi, Musonoi, and Luiswishi open-pit mines. The cobalt content of low-grade ore from the Kolwezi mine is raised by washing, and the washed ore is sent either directly to the electric furnaces at

[11] Dennis, W. H., Recovery of Nonferrous Metals from Pyrite: Mine and Quarry Eng. (London), vol. 13, No. 12, December 1947, pp. 358–362.

Digitized by Google

Jadotville or to the concentrator at Kolwezi, depending upon the content. The Kolwezi concentrator, now being enlarged, will have two stages of crushing, two grinding sections, and two flotation sections. The vast Musonoi copper-cobalt deposit contains large veins especially rich in cobalt, which, in spite of the mixture of ores, are worked separately by selective mining. The Musonoi mine contains ore that attains and sometimes surpasses 6 to 7 percent cobalt, also ores carrying 1.5 to 2 percent cobalt but susceptible of being enriched by concentration up to 7 or 8 percent. These rich products are smelted and reduced in electric-arc furnaces at the Jadotville-Panda plants. The mixed copper-cobalt ore from the Luiswishi mine is sent directly to Jadotville. The cobalt and copper obtained from smelting the cobalt-rich ores and concentrates blend with other metals contained in the charge to form two alloys—a red alloy rich in copper and poor in cobalt and a white alloy rich in cobalt and iron but containing about 15 percent copper. The red alloy is treated in rotary furnaces at the Lubumbashi plant to yield a cobaltiferous slag, which is returned to the electric furnaces at Jadotville to produce white alloy. The white alloy, containing about 45 percent cobalt, is cast into ingots, which are sent to Belgium and the United States for refining.

The greater part of the company reserves of cobalt consists of oxidized copper ores containing less than 0.5 percent cobalt. The cobalt is recovered from these ores by two distinct methods: By an electrolytic process and by smelting in electric furnaces. The ores or concentrates that are poorest in cobalt are sent to the electrolytic copper plant at Jadotville-Shituru, where they are submitted to special treatment to recover the copper and the cobalt. The cobalt, which is recovered as a precipitate, is supplied to the Electrolysis Section. Because cobalt is an electronegative product, electrolytic deposition is possible only in a neutral solution. This is achieved by the electrolysis of a pulp containing cobalt hydrate in suspension. The hydrate acts as a neutralizing agent for the acid that has been liberated by the cathodic deposit. The harmful effect of the solids in suspension (about 100 grams per liter), occlusion of which in the cathodic deposit would lower its grade, is neutralized by mixture of the electrolyte through introducing an air flow through especially designed anodes. Another advantage of this air flow is that it activates reaction of the hydrates of cobalt with the acid. The electrolysis results in consumption of 4.5 kw.-hr. of energy per kilogram of cobalt.

The deposited cathodic cobalt is of the following composition:

	Percent
Co	91–95
Ni	.45–.7
Fe	.08–.2
Mn	.1–.3
Zn	3–5
S	.1–.3
Cu	.01–.03

The cathodic cobalt is refined in a 1,600 kv.-a. triphasic arc furnace. This refining, similar to the operation applied in the production of extra-mild basic steels, permits a slightly oxidizing fusion, which scorifies the manganese, and desulfuration by a reducing slag at a

Digitized by Google

high lime content. The zinc, volatilized in large part at the beginning of the operation, is eliminated by a poling operation. The liquid cobalt is then granulated in water and polished for export. The granules average about 99 percent cobalt. The company production of electrolytic cobalt is about 2,500 tons a year. The capacity of the plant will soon be increased to about 3,300 tons annually.

On the basis of a rate of production of 4,000 metric tons annually, the company reported reserves of cobalt adequate for 40 to 50 years and anticipates that these reserves will increase after further development of its copper deposits.

The operations of Union Minière in Belgian Congo have been described in much detail by its chairman, and much of the above information has been taken from his articles.[12]

Canada.—Production of cobalt in Canada is measured by the quantities of Canadian ores processed and exported, irrespective of the year when mined, plus the cobalt content of concentrates produced by the International Nickel Co. of Canada, Ltd., at Port Colborne, Ontario. Canadian production figures, however, do not include the cobalt recovered by Mond Nickel Co. at its Clydach (Wales) nickel refinery from the nickel-copper ores of the Sudbury district.

According to the Dominion Bureau of Statistics, production of cobalt (content) in Canada was 947,216 pounds in 1951 compared with 583,806 pounds in 1950.

To maintain incentive for the producers, particularly in the Cobalt district of Ontario, to continue to mine cobalt ores in the face of increasing operating costs, three advances in prices were made in the early part of 1951. Effective April 1, it was reported that the following schedule for the purchase of cobalt in ores or concentrates, f. o. b. Cobalt, Ontario, would be in effect:[13]

Cobalt, percent:	*Per pound cobalt*
7 to 7.99	$1.00
8 to 8.99	1.15
9 to 9.99	1.30
10 to 10.99	1.40
11 to 11.99	1.50
12 and over	1.60

Concurrently, it was announced that payment would be made for 100 percent of the cobalt content in silver ores and concentrates. The new price schedule applies to the cobalt in such ores and concentrates delivered by rail to Marmora or by truck at Deloro and is as follows:

Cobalt, percent:	*Per pound cobalt*
Up to 2.99	$0.15
3 to 3.99	.25
4 to 4.99	.35
5 to 5.99	.50
6 to 6.99	.65
7 to 7.99	.80
8 to 8.99	.95
9 to 9.99	1.10

[12] Sengier, E. B., Katanga's Mineral Empire Based on Many Metals: Eng. and Min. Jour., vol. 152, No. 11, November 1951, pp. 86–89; No. 12, December 1951, pp. 92–96.
[13] Northern Miner, vol. 37, No. 2, Apr. 5, 1951, pp. 1, 5.

Digitized by Google

The International Nickel Co. of Canada, Ltd., continued to recover impure cobalt concentrates at its Port Colborne refinery; they are shipped to Clydach, Wales, for refining.

Production of cobalt by Falconbridge Nickel Mines, Ltd., was to begin in 1952. The company has completed a plant at Kristiansand, Norway, to recover cobalt from the matte contained in Sudbury nickel-copper ores.

The Eldorado Mining & Refining (1944), Ltd., continued to produce cobalt-nickel speiss at its Port Hope refinery from pitchblende mined at Port Radium, Northwest Territory. The speiss averages about 14 percent cobalt.

French Morocco.—Production of cobalt concentrate in French Morocco was 6,255 metric tons containing 680 tons of cobalt in 1951 compared with 3,509 tons containing 420 tons of cobalt in 1950. La Société Minière de Bou-Azzer et du Graara, Casablanca, is the sole producer. The cobalt concentrate contains 10 to 12 percent cobalt, as well as some nickel, gold, and silver. During 1951 Deloro Smelting & Refining Co. at Deloro, Ontario, Canada, refined some French Morocco concentrate to metal for the Economic Cooperation Administration; as a result, about 182,700 pounds of metal was delivered to the United States in 1951.

Northern Rhodesia.—Northern Rhodesia was displaced by French Morocco as the second-largest producer of cobalt in the world in 1951. The Rhokana Corp., which has been producing cobalt since 1933, is the sole producer. The output of alloy was 1,978 short tons containing 747 tons of cobalt in the year ended June 30, 1951, compared with 1,954 tons containing 739 tons in 1950. The grade of ore treated was 0.155 percent cobalt in 1951 compared with 0.137 percent in 1950. Concentrates produced contained 1.56 percent cobalt in 1951 compared with 1.39 percent in 1950. Work continued throughout the year on erection of the electrolytic cobalt refinery, which is expected to begin operation early in 1952. The refinery is designed for a production of 1,500 short tons of electrolytic cobalt metal annually.

It was reported that the Economic Cooperation Administration loaned $8,400,000 to Chibuluma Mines, Ltd., to develop new sources of copper and cobalt in Northern Rhodesia. The deposit is near the southern border of Belgian Congo. Reserves of the ore deposit are estimated at 7,300,000 short tons averaging 5.23 percent copper and 0.25 percent cobalt. Production is scheduled to start in 1956. The mine, when in full operation, is expected to yield 16,000 long tons of copper and 500,000 pounds of cobalt annually.[14]

Coke and Coal Chemicals

By J. A. DeCarlo, J. A. Corgan, and Maxine M. Otero

GENERAL SUMMARY

NEW RECORDS were established in 1951 for the production of coke and coal chemicals in the United States. The output of oven and beehive coke combined totaled 79.3 million net tons, a 9-percent gain over 1950 production and a 6-percent increase over the previous record, set in 1948. The new record was made possible by the absence of major work stoppages, an unusually strong demand for coke-oven products, and the availability of adequate coking-coal supplies. The monthly average rate of oven-coke production was unusually uniform throughout the year, ranging from a low of 95.3 percent of capacity in November to a level of 97.9 percent in June; it averaged 96.5 percent for the year, the second highest annual rate on record. This accelerated rate of operation was achieved in spite of the poor condition of a large number of old ovens, which had to be operated carefully. Because of the obsolescence of many ovens and the critical importance of the coke industry to defense mobilization as well as the civilian economy, it became apparent that a coke-expansion program was necessary. Accordingly, on December 5, 1951, the Defense Production Administration established a goal of 84 million net tons of slot-type coke-oven capacity by the end of 1953. The goal set represented a total nearly 10 million tons greater than the capacity actually in place on December 31, 1951. The annual coke capacity of ovens under construction at the end of 1951 totaled 8.1 million net tons; but the new construction did not entirely represent additional capacity, as about 1.4 million tons was for replacement of old batteries.

Beehive-coke ovens, generally marginal producers of coke in periods of heavy demand, produced their largest tonnage since 1943. The monthly rate of beehive-coke production was highest in January, it averaged 23,700 net tons per day but declined thereafter and averaged about 20,000 tons daily during the remaining months of the year. The larger part of the beehive production was shipped to iron blast furnaces and was an important factor in establishing a new record in iron production. Of the total quantity of coke used in blast furnaces in 1951, 10 percent was supplied by beehive ovens, an amount adequate to produce approximately 7 million tons of pig iron.

The consumption pattern of coke in 1951 in general followed that of the preceding year. Increases were attained in consumption by blast furnaces and foundries but the quantity used in manufacturing

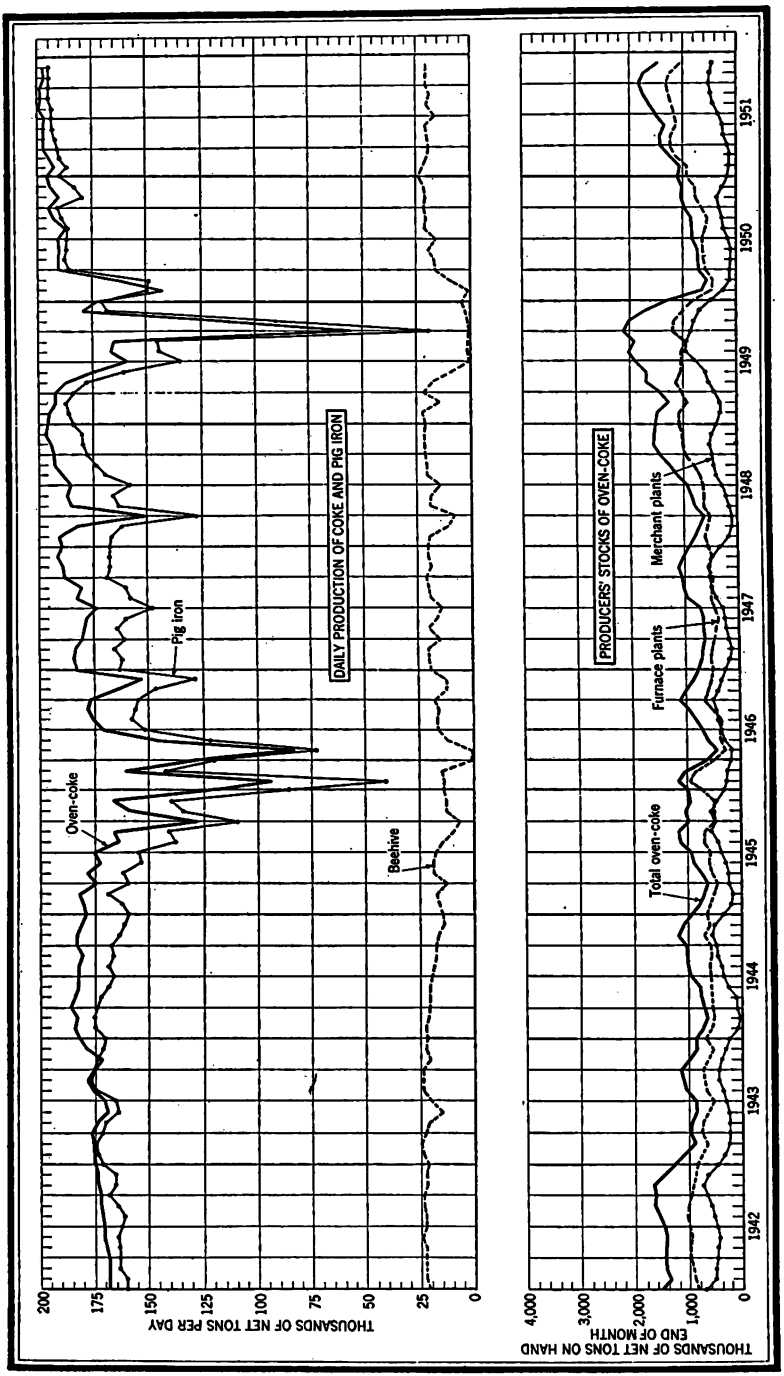

FIGURE 1.—Average daily production of oven and beehive coke and pig iron and producers' stocks of oven coke, 1942–51, by months.

Digitized by Google

producer gas and water gas, and in residential heating declined. The total used for metallurgical purposes (blast furnace and foundry) was the highest on record. Blast furnaces utilized 85 percent of total production in 1951 compared with 83 percent in 1950; foundries, 5 percent; the manufacture of producer gas and water gas, 4 percent; other industrial uses (nonferrous smelting, chemical processing, etc.), 3 percent; household heating, 2 percent; and exports, 1 percent.

The Defense Solid Fuels Administration was established in the United States Department of the Interior in December 1950 to direct mobilization of the solid-fuels industries (including coke and coal chemicals) to meet defense requirements. Functions with respect to distribution of coal chemicals produced at oven-coke plants were delegated to the Secretary of Commerce, effective May 16, 1951. As the claimant agency for the coke industry, DSFA ascertained the requirements of the coke producers for materials to be used in maintenance, repair and operation, or new construction. Starting with the fourth quarter of 1951, construction permits were issued by this agency, and building materials under priority control were allocated to approved projects. Applications for necessity certificates for rapid tax amortization of the capital costs of new construction were processed by DSFA for the Defense Production Administration. Statistical and technical assistance was provided the DSFA by the Bureau of Mines in carrying out the defense program for expanding coke-making capacity.

A number of defense regulations were issued relating to coke and coal chemicals. The National Production Authority issued Priority Regulation 1—Inventory Control—effective September 18, 1951, to prevent accumulation of excessive inventories of critical materials by limiting the quantity that could be ordered, received, or delivered. Benzol was the only coal chemical originally controlled, but the regulation was amended October 22, 1951, to include naphthalene, phenol, and pyridine.

The Office of Price Stabilization placed price ceilings on coke and coal chemicals on March 16, 1951, under Supplementary Regulation (S. R.) 13 to the General Ceiling Price Regulation. Under this regulation, coke producers were permitted to adjust prices to reflect increases in costs of raw materials, principally bituminous coal, provided that the increases put in effect would not cause the producers' operating margin to exceed that of the base period, January 1—December 31, 1950. S. R. 13 was amended subsequently as follows: On May 16, 1951, it was altered to include distributors as well as producers; and on June 30, the expiration date was extended to Sept. 30, later to Dec. 31, 1951, and then to Feb. 29, 1952.

According to the Bureau of Mines survey of man-hours and active days in the coke industry in 1951, there was an average of 22,058 men working per active day representing a total of 64,102,990 man-hours in the oven-coke industry. These figures represent an increase of 1,116 men working per active day and 3,509,903 man-hours over 1950. In the beehive segment of the industry, the average number of men working per active day increased from 3,405 in 1950 to 3,657 in 1951, and the man-hours worked advanced from 5,267,918 to 6,087,503. Productivity at both oven and beehive plants increased slightly as output per man-hour at the coke-oven plants rose from

Digitized by Google

1.19 tons in 1950 to 1.20 in 1951; at beehive plants the increase was from 1.12 tons per man-hour in 1950 to 1.22 in 1951. Productivity in the oven-coke industry is not accurately indicated by the statistics, as the number of man-hours devoted to coke production, as such, cannot be separated from those worked in the chemical-recovery plants. If such separation were possible, however, the figures would undoubtedly show a higher output per man-hour at oven-coke plants than at beehive installations.

The production of coal-chemical materials, which usually parallels that of oven coke, also reached a new peak. The output of ammonia and tar increased 8 percent each, of crude light oil 9 percent, and of gas 7 percent over 1950. An increased production of basic chemical raw materials resulted in substantial gains also in the production of ammonium sulfate, ammonia liquor, and virtually all of the other light-oil and tar derivatives. In spite of the gains indicated above, demand for some of the coal chemicals, particularly benzol and naphthalene, was greater than the supply available from domestic

TABLE 1.—Salient statistics of the coke industry in the United States, 1937 and 1950–51

	1937	1950	1951
Coke production:			
Oven...net tons	49,210,748	66,890,618	71,987,172
Beehive...do	3,164,721	5,827,420	7,343,530
Total...do	52,375,469	72,718,038	79,330,702
Percent oven	94.0	92.0	90.7
Producers' stocks of coke, end of year...net tons	2,595,287	1,110,714	1,482,972
Exports, all coke...do	526,683	397,801	1,026,730
Imports, all coke...do	286,364	437,585	161,639
Apparent consumption, all coke...do	51,271,929	73,416,519	78,093,353
Disposal, all coke sold or used:			
Blast furnace...do	36,751,969	60,918,549	67,440,987
Foundry...do	2,038,822	3,523,396	3,805,686
Other industrial (including producer and water gas)...do	4,597,894	6,366,497	5,603,262
Domestic...do	8,107,518	2,565,176	2,087,934
Receipts per ton of coke sold (merchant sales):			
Blast furnace	$4.22	$13.95	$14.99
Foundry	$7.91	$19.78	$21.81
Water gas	$6.25	$15.02	$15.73
Other industrial	$5.48	$13.55	$14.09
Domestic	$6.43	$13.59	$14.43
Coal-chemical materials produced:			
Tar...gallons	603,053,288	739,868,767	795,311,283
Ammonium sulfate or equivalent...pounds	1,506,431,251	1,849,127,582	1,995,546,999
Gas...M cubic feet	757,628,942	979,592,988	1,052,280,603
Burned in coking process...percent	37.04	36.81	36.19
Surplus sold or used...do	61.12	61.54	62.09
Wasted...do	1.84	1.65	1.72
Crude light oil...gallons	187,054,346	260,856,875	284,496,933
Yield of coal-chemical materials per ton of coal:			
Tar...gallons	8.67	7.79	7.78
Ammonium sulfate or equivalent...pounds	21.84	19.89	19.82
Gas...M cubic feet	10.89	10.32	10.29
Crude light oil...gallons	2.86	2.81	2.82
Value of coal-chemical materials sold:			
Tar	$18,456,483	$37,558,999	$43,546,155
Ammonia (sulfate and liquor)	$16,048,325	$31,322,588	$36,032,105
Gas (surplus)	$72,961,697	$132,247,656	$138,300,299
Crude light oil and derivatives	$20,215,404	$53,819,463	$78,024,932
Other coal-chemical materials [1]	$4,442,929	$19,421,444	$28,044,466
Total value of all products [2]	$411,706,484	$1,278,625,062	$1,474,406,800

[1] Naphthalene, tar derivatives, intermediate light oil, and miscellaneous materials.
[2] Includes value of coke and breeze produced and tar used as fuel by producers.

sources. Substantial quantities of benzol and naphthalene were imported. Although supplies of these two commodities were limited, nevertheless they were not placed under allocation control. However, action was taken by NPA from time to time on some of the scarcer chemicals, particularly toluol, to provide for its use in explosives and on benzol, to alleviate spot shortages. The price of coke-oven benzol under price ceilings averaged $0.34 per gallon. Petroleum benzol, however, was produced in increasing quantities in 1951 to make up the difference between demand and coke-oven output. It averaged $0.47 per gallon, according to data published by the United States Tariff Commission.

The total value of coal-chemical materials sold amounted to $323.9 million, a gain of 18 percent over the 1950 figure. The value of all coke-oven products, whether used by producers or sold, totaled $1.5 billion, a new record.

TABLE 2.—Statistical summary of the coke industry in the United States in 1951

	Slot-type ovens	Beehive ovens	Total
Coke produced—			
At merchant plants:			
Net tons	13,190,550	(2)	(2)
Value	$218,174,099		
At furnace plants: [1]			
Net tons	58,796,622

SCOPE OF REPORT

The statistics in this chapter, except where otherwise noted, are based on data voluntarily supplied to the Bureau of Mines by coke-plant operators within the continental limits of the United States. Except for minor variations, the characteristic form and manner of presentation of material developed in coke chapters for preceding years are followed in this report, carrying the Bureau's series on coke and coal-chemical materials through 1951. For convenience, most of the statistical tables herein include comparable data for three or four preceding years.

These statistics are confined to the operations of high-temperature beehive and slot-type coke-oven plants. To present data in this chapter on the carbonization of coal by other processes, salient statistics for gas retorts are shown in table 4. Statistics on medium- and low-temperature carbonization have also been shown in recent years; but, as less than three producing companies reported production in 1951, data are withhheld to prevent disclosure of individual company operations. When compared with the production of coke and related products from slot-type and beehive-coke ovens, production from retorts and low-temperature ovens was not an important factor in supply and requirements.

Some coke is made by processes not included in this report, namely, from the refining of petroleum and crude tar. Data for 1951 showed that the production of petroleum coke totaled 3,795,400 net tons and the output of pitch coke, as reported by the United States Tariff Commission, totaled 45,000 net tons.

The standard unit of measurement in the coke industry in the United States is the short or net ton of 2,000 pounds. Unless otherwise specified, it is the unit employed throughout this chapter.

The term "coke" as used throughout this report refers only to the larger sizes (usually one-half inch plus) from which the smaller sizes have been screened. The fine coke, which is separated by screening, is known in the industry as "breeze"; that term is used by the Bureau of Mines to designate this material.

[1] Value for tar up to and including 1917 represented that of tar "obtained and sold" which did not always include value of tar used by producer. Beginning with 1918, tar used by producer is specifically included. Value of breeze produced at oven-coke plants is included for those years for which it was reported, namely, 1916, 1917, and 1919–51. For other coal-chemical materials, only value of those sold is included. Value of breeze produced at beehive plants is not included, as it has usually been much less than a million dollars.

[2] No accurate data on value of the coal-chemical materials available.

MONTHLY AND WEEKLY PRODUCTION

Statistics on monthly production of coke in tables 6 to 8 are based upon reports received from producers. Weekly production of beehive coke in table 9 was estimated from reports of carloadings received from all coke-carrying railroads. The totals in these tables have been adjusted to the total ascertained by an annual canvass of the producers.[1]

TABLE 6.—Coke produced in the United States and average per day, 1937 and 1949–51, by months, in net tons [1]

Month	1937		1949		1950		1951

[1] Before 1941 daily average production of beehive coke was calculated by subtracting Sundays and holidays in each month; 1942–51 daily average has been calculated by dividing total monthly production by total number of days in month.

[1] Data on weekly production of beehive coke are published by the Bureau of Mines in the Weekly Anthracite and Beehive-Coke Report and monthly data for both oven and beehive coke are summarized in the Monthly Coke Report, available upon request to the Publications Distribution Section, Bureau of Mines, Washington 25, D. C.

PRODUCTION BY FURNACE AND MERCHANT PLANTS

In 1922 the Bureau of Mines began classifying oven-coke plants into two groups, "furnace" and "merchant." This grouping is maintained in the interest of those who may wish to follow the carbonizing activity of the iron and steel industry proper and is used wherever applicable throughout this chapter. Under this classification, furnace plants may be defined as those under direct ownership of or having a financial affiliation with iron and steel companies whose main business is the production of blast-furnace coke for their own use. All other plants are classified as "merchant" and include those that manufacture metallurgical, industrial, and domestic grades of coke for sale on the open market; coke plants associated with chemical companies gas utilities; and plants affiliated with local iron furnaces where only a small percentage of the total annual output is used for blast-furnace fuel.

Production of oven coke by these two groups in 1951 and for several previous years is shown in table 10. These data show that, through 1951, production at furnace plants increased 63 percent since 1937, while output at merchant plants showed little change in actual tonnage, although the number of plants and the percentage of the total oven-coke output produced by this group dropped drastically. A number of economic factors caused this shift in oven-coke production. One of the principal reasons for the steady decline in number

Digitized by Google

of merchant plants in the past 2 decades has been the expansion and extension of natural-gas pipelines into areas formerly served by coke-oven gas. As a result, affected gas-utility companies either closed the coke plants or sold them to iron and steel companies, where the plants were located favorably in relation to blast-furnace installations. There has been a tendency on the part of the iron and steel producers to integrate their coking and steel-making facilities more closely. For example, in the 5-year period, 1932–36, furnace plants produced 65 percent of the total oven-coke output; in 1937–41, 74 percent; in 1942–46, 77 percent; and in 1947–51, 81 percent. This trend was expected to continue because virtually all of the expansion of coke-oven facilities underway at the end of 1951 was in the furnace group.

TABLE 10.—Number and production of oven-coke plants connected with iron furnaces and of other oven-coke plants in the United States, 1913, 1918, 1937, and 1949–51

Year	Number of active plants		Coke produced (net tons)		Percent of production	
	Furnace plants	Merchant plants	Furnace plants	Merchant plants	Furnace plants	Merchant plants
1913	20	16	9,277,832	3,436,868	73.0	27.0
1918	36	24	19,220,342	6,777,238	73.9	26.1
1937	43	42	36,134,209	13,076,539	73.4	26.6
1949	55	31	48,109,559	12,112,922	79.9	20.1
1950	55	30	54,543,796	12,346,822	81.5	18.5
1951	56	28	58,796,622	13,190,550	81.7	18.3

PRODUCTION BY STATES AND DISTRICTS

Production of coke in 1951 increased over 1950 in all but 2 of the 23 States where coke ovens were active. The largest percentage increases were in Virginia, Massachusetts, Colorado, and Maryland, with gains of 45, 30, 24, and 21 percent, respectively. The largest tonnage increases were reported for Pennsylvania, Ohio, and Indiana. These 3 States combined made 54 percent of the gain over 1950.

Production of oven coke for 1951 and prior years, by geographic areas, is shown in table 13. The States west of the Mississippi River (California, Colorado, Texas, Utah, and Washington) increased production by a larger percentage than any other area since 1937, a gain of 444 percent. The area comprising Alabama, Kentucky, Tennessee, and West Virginia increased production substantially over this period, with advances of 68 percent, followed by Ohio, with a gain of 66 percent.

Coke-production facilities have been more or less located in recent years with regard to iron production, gas manufacture, or chemical processing. In the early days of the coke industry, when beehive ovens were the principal source of metallurgical coke, production was limited to States producing coking coal. However, with development of the slot-type oven and its adaptation to metallurgical coke production and gas manufacture, coke plants have been built great distances from sources of coal and near steel and gas consuming centers. As a consequence, 13 States where oven coke was produced did not mine any coking coal in 1951, and all coal carbonized was shipped in.

NUMBER AND TYPE OF OVENS

Slot-Type Coke Ovens.—One of the major problems confronting the coke industry in 1951 was to provide enough coal-carbonizing capacity to support the double burden of the National Defense Program and accelerated industrial activity. A total of 696 new slot-type coke ovens was placed in operation during the year; 359 ovens were taken out of production, a net gain of 337 ovens. Most of the 359 ovens were shut down for rebuilding, although 1 coke plant (Niagara Mohawk Power Corp., Utica, N. Y., plant) with 42 ovens closed permanently, and a few ovens at other plants were blocked off and will not produce coke again unless the batteries are rebuilt. The limited supply of refractories (coke-oven shapes) and other essential building materials limited the number of new ovens completed in 1951.

Although the coke industry had built a large number of new slot-type coke ovens (4,728) in the past decade, at the close of 1951 over half the total number of ovens in existence were at least 20 years old. This statement is not to be construed as placing the maximum life expectancy of coke ovens at 20 years, as a number of older batteries producing in 1951 were in good operating condition. However, coke-oven operators and builders agree that, with few exceptions, ovens over 20 years old become increasingly difficult to maintain. Moreover, the length of efficient service that may be rendered by a new coke-oven battery depends on operating conditions at each plant and on the decision of the owners as to when maintenance and repairs become excessive.

In an effort to maintain not only the existing capacity by rebuilding worn-out batteries but also to erect additional capacity commensurate with increased blast-furnace requirements, the coke industry had the largest number of ovens under construction at the close of the year since World War I. In all, 1,446 new ovens were under construction on December 31, 1951, and contracts for a number of new batteries were pending. Except for one battery of coke ovens of English design, all other ovens under construction were being built by the Koppers Co. and the Wilputte Coke Oven Division of Allied Chemical & Dye Corp. Of the 15,319 ovens in existence at the end of the year, 35 percent were Koppers; 41 percent, Koppers-Becker; 11 percent, Semet-Solvay; 12 percent, Wilputte; and 1 percent, all other kinds.

Beehive Ovens.—Data on the number and coking capacity of beehive ovens have been obtained for many years by the Bureau of Mines, but no attempt was made until recently to separate the operable ovens from the total in existence. This distinction is made in table 20, which shows capacity at the end of 1951. Old ovens, not capable of producing coke without extensive repairs or rebuilding, comprised 23 percent of the total beehive-coke capacity reported in existence. Therefore, for practical purposes, only the serviceable ovens should be considered available sources of coke. The heavy demand for coke in 1951 is reflected in the fact that 96 percent of the ovens considered to be in good operating condition actually produced coke in 1951.

April	12,727	August	12,927	December	13,151

CAPACITY OF OVEN-COKE PLANTS

The basis for calculating the potential annual maximum coke capacity of a plant is the minimum coking time necessary to produce a coke with qualities suitable for its intended use. For this reason, the potential capacity of a plant may change from year to year, depending on the age and condition of the ovens, the character and quality of the coal carbonized, the grade of coke required, and other economic factors. The capacity reported to the Bureau of Mines by the coke-producing companies may therefore differ from the designed or rated capacity estimated by the coke-oven builders at the time of construction. It is believed, however, that the potential capacity shown in table 22 is a reliable measure of the practical operating capacity for the years given.

The potential annual coke capacity on December 31, 1951, was 2 percent higher than for the preceding year. This increase was due entirely to expansion of carbonizing capacity at plants associated with iron and steel works (furnace plants) as capacity of merchant plants dropped 3 percent. The factors contributing to the steady decline in the capacity of merchant plants have been mentioned in a preceding section of this chapter and need not be repeated here. That the decline in merchant-plant capacity would continue was evidenced by the new ovens under construction. Of the 8,134,500 tons of potential capacity under construction at the end of 1951, 7,466,200 tons (92 percent) was at furnace plants.

The Bureau of Mines has collected monthly data on oven-coke production for many years. The rate of oven operations may be calculated from these data. Table 23 shows the percentage of coke capacity utilized each month for 1951, with certain preceding years for comparison. The average monthly rate of production for 1951 was the second highest on record and illustrates the high-level continuity of oven operations throughout that year. This outstanding record, when the poor condition of a large number of old ovens is considered, clearly indicates the skill and ingenuity of the coke-plant operators.

[1] Capacity of all ovens in existence, whether active or idle, based upon maximum daily capacity times days in month.

QUANTITY AND COST OF COAL CHARGED

Coke ovens (slot-type and beehive) used a record quantity of bituminous coal in 1951—113.7 million tons. This figure represented a 9-percent gain over the 1950 total and was 6.4 million tons (6 percent) greater than the previous peak consumption of 1948. This new mark was attributed to the increased demand for coke (which, in turn, necessitated the maintenance of high operating rates at both oven- and beehive-coke plants) and to the absence of any major work stoppages in the steel and bituminous-coal industries. Because of the continuous nature of the coking process and the strong demand for the coke produced, monthly consumption of coal in coke ovens is generally uniform and does not vary because of seasonal conditions (table 24).

Pennsylvania continued to lead all coke-producing States in the carbonization of coal, processing 25 percent of the coal carbonized in slot-type ovens and 86 percent of the total used in beehives. Ohio ranked second, with 15 percent of the total used in slot-type ovens, followed by Indiana, Alabama, and New York, which, combined, consumed 29 percent. These 5 States, therefore, consumed 69 percent

Digitized by Google

of the total, compared with 31 percent for the other 17 States where oven coke was produced. The practice of mixing or blending a small percentage of anthracite fines, which was begun during World War II, was continued at 12 plants in 1951. A total of 237,100 tons was used for this purpose during the year.

As coal is the chief item of expense in the manufacture of oven coke (normally representing about 80 percent of total costs), its cost has a definite influence on coke-oven operations and is extremely important to coke-plant operators. The cost of coal delivered to the coke plants had been increasing steadily since the beginning of World War II and reached a new high in 1951. The average cost of coal at oven-coke plants in 1951 increased $0.27 per ton (3 percent) over 1950 and was 143 percent higher than the figure for 1940. A large part of the coal used at oven-coke plants must be transported great distances, increasing its cost at the ovens. Of the States for which figures on coal costs can be shown, Minnesota, Illinois, New York, and Indiana, in the order named, had the highest costs, while West Virginia, Alabama, and Pennsylvania had the lowest owing to their proximity to the coal fields.

The average cost of coal at beehive ovens in 1951 was the highest on record, yet it was lower than at oven-coke plants because the beehive plants generally were near the mines. In recent years, however, many beehive operators have had to truck part, or in some instances all of their coal requirements, substantially increasing their coal costs. In the Connellsville region, Pennsylvania, in 1951, coal was transported by truck as far as 40 miles to some beehive plants. Charges on such hauls approximated $2 per ton. This additional expense for many plants has influenced the average cost of coal for the entire beehive industry. The average cost of coal in 1951 ($6.15 per ton) was 8 percent above the 1950 average and 209 percent higher than the 1940 figure. Partly because of trucking charges, Pennsylvania had the highest costs and West Virginia the lowest.

PREPARATION AND SOURCE OF COAL

Washed and Unwashed Coal.—An outstanding development in the coke industry in 1951 was the large increase in the percentage of washed coal carbonized in slot-type ovens. Although coal cleaning in the United States predates erection of the first oven-coke plant in 1893, the practice did not become an important factor in coke-plant operations until recent years. However, gradual depletion of the reserves of the best quality coking coals and steady rise in mechanized mining, with its attendant increase in impurities, has necessitated washing or cleaning a larger part of the available coals. This is due to the fact that the quality of the coke produced depends more upon the character and quality of coal carbonized than upon oven design and carbonizing practice. Coals having high ash and sulfur contents will produce a coke having similar chemical characteristics. Coke of high ash or sulfur content is not desirable for use in blast furnaces, foundry cupolas, miscellaneous industrial operations, or residential heating.

Washed coal charged into slot-type ovens in 1951, according to reports submitted by coke-plant operators, amounted to 50 percent of the total tonnage of bituminous coal carbonized, compared with 40 percent in 1950 and 28 percent in 1946. The proportion of washed coal charged into beehive ovens was less than in slot-type ovens, being 17 percent of the total in 1951. Most of the cleaning or washing was done at the coal mines. In 1951 bituminous coal cleaned at the mines was used by 50 oven- and 13 beehive-coke plants and amounted to 85 percent of the washed coal carbonized. The remainder (7.7 million tons) was washed at coke plants having cleaning facilities.

Blending.—The practice of blending or mixing various types of coal to obtain a coke relatively free from shrinkage, cracks, and with a minimum of breeze is a common practice among oven-coke plant operators. A better coke usually can be obtained from a proper blend of 2, 3, or more different coals than from any one alone. Blending has several objectives and involves many important factors which must be considered by the oven-coke plant operator if the primary objective of producing economically a quality coke is to be achieved. It also permits use of a coal that has good coking properties but may be objectionable due to an excessive ash, sulfur, or phosphorus content which makes it unsuitable as a 100-percent charge. Thus, in addition to providing a means of controlling the quality and strength of the coke and the yield of coproducts, blending permits flexible operations at oven-coke plants and use of a far wider variety of coals. All oven-coke plants mix or blend coals before charging them into ovens. The mixing of coal of different volatile content was practiced at 79 oven-coke plants in 1951. Of these, 55 used high- and low-volatile coals; 19, high-, medium-, and low-; 3, high- and medium-; and 2, low- and medium-volatile. Of the plants that did not blend coals of different volatile content, 2 plants used straight high-volatile and 3, medium-volatile. The proportion of coals of different volatile contents mixed before charging into ovens, where practiced, varies widely from plant to plant. Generally, about 20 percent low-volatile coal is mixed with high-volatile, although some plants reported the use of as much as 50 percent low-volatile. A study of the reported volatile content of all coal used by oven-coke plant operators in 1951 showed that about 63 percent was high-volatile, 13 percent medium-volatile, and 24 percent low-volatile. These proportions have changed but slightly during the past decade, with gradual increase in the use of low-volatile coals.

Sources.—More interest has been shown in recent years in the reserves and sources of coking coal than ever before. The tremendous demand for coking coal, caused by two great wars and the high level of industrial production since the end of World War II, has made serious inroads into the reserves of our better coals. Coke is essential in the manufacture of pig iron, which, in turn, is required to make steel—a vital element in our modern industrial economy. As all coals will not fuse and form a coherent, strong, porous structure when heated at high temperatures (above 1,000° C.), known reserves of established coking quality are extremely important to our economy. The Bureau of Mines has studied the coking qualities of a number of domestic coals. The results of this research have been compiled in a series of reports of investigations.

The largest concentration of coking coal in the United States is found in the Appalachian region, which extends from Alabama to Pennsylvania. States comprising this region supplied 94 percent of all coal carbonized in 1951. West Virginia furnished 35 percent; Pennsylvania, 34 percent; Kentucky, 13 percent; Alabama, 9 percent; and Virginia, 3 percent. The remainder was obtained from various other States, particularly Utah, Oklahoma, Colorado, and New Mexico. The better quality high-volatile and medium-volatile coking

SHIPMENTS BY RAIL, WATER, AND TRUCK

Rail shipments represented 92 percent of the total movement of large coke and 87 percent of the breeze in 1951. Truck shipments declined sharply from 1950 and represented only 5 percent of the total. Shipments of coke by water were relatively small, only 3 percent of the total.

Shipments of oven coke usually approximate less than 40 percent of the total production because many of the larger coke plants are integrated with iron blast furnaces; hence, the large coke suitable for metallurgical use is transferred to the furnaces without leaving the producing site. Only 26 percent of all coke produced at furnace plants moved outside the plants in 1951, whereas 83 percent of the coke produced by merchant plants was shipped.

Beehive-coke plants are generally at or near the mines, and virtually all of the production must be shipped to consuming centers. The bulk of the beehive coke moves by rail, only a small amount by boat and truck. The location of beehive plants precludes any large movement by water, and trucking long distances is seldom economical.

DISTRIBUTION OF OVEN AND BEEHIVE COKE

Table 35 summarizes the distribution of coke and breeze in 1951.[3] As large coke is separated into broad use classifications, the totals for each State are indicative, therefore, of the size and nature of the coke market in particular States.

Coke has numerous industrial applications to explain its widespread distribution; however, as the bulk of the coke consumption in the United States is for smelting iron ore, a few States, with a concentration of heavy industry, are the principal consumers. In 1951, Pennsylvania, the leading pig-iron-producing State also led in coke consumption, with 28 percent of the United States total. Ohio was second in consumption, with 18 percent of the total, followed by Indiana, Illinois, New York, and Alabama, in the order named. The last 4 States combined consumed 32 percent of the total; the 6 States mentioned therefore consumed over three-fourths of all the coke used in the United States. The remaining coke was distributed among the other 42 States and the District of Columbia, and less than 1 percent was exported by the producing companies.

Foundry coke was distributed more widely than coke for blast furnaces, as it was used in 46 States; Michigan alone consumed 17 percent. Coke was used in 9 States in manufacturing producer gas; gas utility companies in New York consumed 34 percent of the total. The use of coke in manufacturing water gas was reported for 23 States; New York, West Virginia, and Virginia consumed 55 percent of the total used for this purpose. Coke for "other industrial" uses was shipped to every State and the District of Columbia, and 38 States received coke for household heating.

[3] Detailed statistics on coke distribution have been published by the Bureau of Mines in Mineral Market Report MMS No. 2092 available on request to the Anthracite and Coke Sections, Bureau of Mines, Washington 25, D. C.

CONSUMPTION OF COKE

The apparent consumption of coke in the United States in 1951, based on production, imports, exports, and changes in producers' stocks, increased 6 percent over 1950 and reached 78.1 million net tons. This figure was the highest ever attained and exceeded the 1948 record by 4.3 million tons. Consumption by iron blast furnaces rose substantially over 1950—9 percent. These furnaces, which have always utilized the bulk of the coke produced in the United States, used 85 percent of the total apparent consumption in 1951 compared with only 73 percent in 1937. The recent changes in the consumption pattern for coke have been due to gradual expansion of blast-furnace capacity, while requirements for gas making and residential heating have declined because of increased competition from

Digitized by Google

natural gas and fuel oil. It was expected that coke consumption would continue the upward trend during the next several years after 1951, because blast-furnace coke requirements would increase in direct ratio to expansion of blast-furnace capacity.

The fuel efficiency of blast furnaces, after improving in 1949 and 1950, declined slightly in 1951 (table 37). The quantity of coke required to produce 1 ton of pig iron increased 5.6 pounds over 1950 to 1,848.7 pounds; and for pig iron, including ferroalloys, the increase was 5.2 pounds to 1,870.7.

TABLE 36.—Apparent consumption of coke in the United States, 1913, 1918, 1937, and 1949–51, in net tons

Year	Total production	Imports	Exports	Net change in stocks	Apparent United States consumption [1]	Consumed by iron furnaces [2]		Remainder consumed in other ways

[1] Production plus imports minus exports, plus or minus net changes in stocks.
[2] American Iron and Steel Institute; figures include coke consumed in manufacture of ferro-alloys.
[3] Data not available.

TABLE 37.—Coke and coking coal consumed per net ton of pig iron made in the United States, 1913, 1918, 1937, and 1949–51

Year	Coke per net ton of pig iron and ferro-alloys [1] (pounds)	Yield of coke from coal (percent)	Coking coal per net ton of pig iron and ferro-alloys (pounds calculated)	Year	Coke per net ton of pig iron and ferro-alloys [1] (pounds)	Yield of coke from coal (percent)	Coking coal per net ton of pig iron and ferro-alloys (pounds calculated)
1913	2,172.6	66.9	3,247.5	1949	1,895.8	69.6	2,723.9
1918	2,120.7	66.4	3,193.8	1950	1,865.5	69.9	2,668.8
1937	1,830.6	70.3	2,604.0	1951	1,870.7	69.8	2,680.1

[1] American Iron and Steel Institute; consumption per ton of pig iron only, excluding furnaces making ferro-alloys, was 2,172.6 pounds in 1913, 2,120.7 in 1918, 1,806.7 in 1937, 1,870.4 in 1949, 1,843.1 in 1950, and 1,848.7 in 1951.

Tables 38 and 39 summarize the disposal of oven and beehive coke in 1951, by principal end uses. A large proportion of the oven-coke output is used by producers in integrated blast furnaces, whereas nearly all of the beehive-coke production is shipped to consumers. The proportion of blast-furnace coke requirements supplied by furnace plants has been increasing in recent years, with substantial expansion of carbonizing facilities at the furnace plants. This group of plants supplied 93 percent of the total oven coke used in blast furnaces in 1951 compared with 91 percent in 1940. Merchant plants supply the bulk of the coke for other industrial purposes and domestic heating. In 1951 the merchant plants supplied 85 percent of all coke used in foundries, 81 percent for other industrial purposes (including gas manufacture), and 81 percent of the coke used for domestic heating. Beehive ovens normally ship a larger proportion of their production to blast furnaces than do the oven-coke plants. In 1951, 87 percent of total beehive-coke production was destined to blast furnaces.

STOCKS OF COKE AND COKING COAL

Production was slightly higher than requirements of coke during 1951, and stocks at producers' plants at the year end were higher than at the beginning. Stocks of coke of all grades at oven-coke plants increased, blast-furnace coke rising 34 percent, foundry 91 percent, and domestic and other grades 34 percent. Normally, furnace plants carry only a few days' supply of coke in reserve because

Digitized by Google

of the vertical integration of their operations. Merchant plants, however, often find it necessary to stock coke, especially the domestic heating sizes. Oven coke stocked at furnace oven-coke plants on December 31, 1951, was equivalent to only 6 days' production. Reserves held by merchant plants were equivalent to 13 days' production. Producers' stocks of beehive coke, which usually are smaller than stocks carried by oven-coke plants, amounted to less than 1 day's production.

Stocks of coal at all oven-coke plants reached the highest figure on record during January 1951, when stocks were adequate for a calculated 60.9 days' operations at the rate of coal consumption prevailing at that time. Stocks declined to a low point of 50 days' supply in July but increased in subsequent months and, at the end of the year, sufficed for a 54.5 days' supply.

The maintenance of adequate stocks of bituminous coal at oven-coke plants is essential because of the continuous nature of the carbonizing process. A 30 days' supply is the minimum desired by most oven-coke plant operators to safeguard against disruption in the flow of coal to the ovens. Coke plants on the upper Great Lakes, which are supplied principally by Lake carriers, build up inventories during the shipping season to have enough tonnage to carry them through the winter. These plants usually have a stockpile aggregating 4 to 5 months' supply at the end of the Lake shipping season.

TABLE 40.—Summary of producers' stocks of coke at all coke plants in the United States on Jan. 1, 1937, and 1948–52, in net tons

	1937	1948	1949	1950	1951	1952

VALUE AND PRICE

The term "value," as used in this report, is the value of the coke at the ovens as reported by producers. For that part of the output sold, the value is the amount received for the coke f. o. b. ovens. However, the greater part of the coke produced in the United States is made in ovens operated by corporations, which not only mine the coal used in manufacturing coke but also operate blast furnaces and steel mills, consuming the entire output of their ovens. Under such conditions, fixing a value for coal charged and for coke produced is governed by established accounting procedures. For example, at some plants the costs of coke to the furnace department equals the cost of production; at others, a margin of profit is added; or the reported value is based on what the coke would cost if purchased. The line between sales and interdepartmental transfers is difficult to draw among such affiliated interests, as a large part of the furnace coke reported as sold actually goes to iron furnaces that are in some way connected with the coke producers.

The average value of all coke produced in 1951, measured in the above way, was $14.11 per ton, the highest figure ever recorded and a gain of 5 percent over 1950 (table 44).

The average price received for each ton of coke sold, f. o. b. ovens (merchant sales), in 1951 established a new record and was 7 percent over the 1950 figure. Table 45 shows average receipts from sales classified by uses and by States. It will be noted that prices vary notably with the distances from the mines. Thus, the highest average prices were those reported for the New England and Lake Dock States, where the coal must be hauled great distances.

FOREIGN TRADE [3]

Imports.—Statistics on imports of coke into the United States include coke made either from coal or petroleum, although the two types are separated in the export statistics. The improvement in the supply of coke in the United States during 1951 resulted in a 63-percent decrease in imports. Canada, as in prior years, was the principal source of imported coke, supplying 98 percent of total imports in 1951. The bulk of the coke imported in 1951 passed through the Montana-

[3] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Idaho and Michigan customs districts. Coke entering through the Montana-Idaho customs district probably was used for smelting nonferrous metals, while that entering the Michigan gateway was used for miscellaneous industrial purposes and residential heating.

Exports.—Exports of metallurgical and foundry coke were placed under Government control for the first quarter of 1951. A quota of 15,000 short tons was established for all foreign countries, and similar quotas were set for each succeeding quarter. Shipments to Canada (not subject to licensing) were not included in these quotas. Licensing of exports was placed under the jurisdiction of the Office of International Trade, United States Department of Commerce. At the time the quotas were established, that agency announced that additional shipments of coke would be licensed if, after conference with the National Production Authority and Defense Solid Fuels Administration, it was found that production exceeded United States requirements. Quotas were exceeded in the last three quarters of 1951 as large quantities of coke, not required along the Atlantic seaboard, were licensed for shipment abroad. Consequently, exports to Europe were the highest on record, and the gain in shipments to Canada raised the total to over 1 million tons, the highest since 1946. This total, however, equaled only 1 percent of the apparent United States consumption for the year.

TECHNOLOGY

Substantial contributions were made to coke technology in 1951 by Federal Government and State agencies, coal-research laboratories, colleges, and individual companies. Highlights of the Bureau of Mines work in 1951 were the following:

Development of a new experimental coke oven at the Tuscaloosa, Ala., Experiment Station. This experimental oven was wider and much larger than test ovens formerly used, and a limited number of tests indicated that the oven closely duplicated full-scale performance.[4]

An extraction technique was developed during 1951 that may be commercially applicable to the preparation of low-ash carbonaceous material in manufacturing electrode carbon.[5]

A résumé of the special studies made by the Bureau of Mines from July 1, 1950, to June 30, 1951, inclusive, on coking-coal reserves, carbonizing properties, plasticity, expansion, and oxidation of various coals was contained in the Sixteenth Annual Report of Research and Technologic Work on Coal.[6] This report listed the original publications containing detailed information on the individual studies.

Shortages of benzol and sulfur during 1951 intensified work on improved production methods for these commodities. In an effort to increase benzol production, the Donner-Hanna Coke Corp., Buffalo, N. Y., installed a refrigeration unit in its light-oil recovery system. By refrigerating the wash oil used to absorb the light oil from the gas stream, it was claimed that the scrubbing efficiency was improved, which, in turn, would increase benzol production substantially. The shortage of sulfur focused a great deal of attention on recovering it from coke-oven gas. The Szombathy liquid-catalyst process created new interest in the subject.[7] A pilot plant using this new process was installed by the Heinrich Koppers Co., Essen, Germany, at the Mainz coke plant.

A comprehensive review of significant technical developments throughout the world in the field of coal carbonization was published in 1951.[8] This review included lists of original publications concerned with studies of raw materials, coke and coal chemicals, improvements in coke-plant equipment and operations, and procedures for analysis and testing of coal, coke, and coal-chemical materials.

WORLD PRODUCTION

World production of coke in 1951, estimated at 203.7 million metric tons, established a new alltime peak, exceeding the 1950 record by 12 percent. The figure shown is for large coke produced at high temperatures in conventional slot-type or beehive-coke ovens only and does

not include coke breeze, gashouse (retort) coke, low-temperature coke, and char. As the data shown are for coke used principally for industrial purposes, it is evident that the more highly industrialized nations are the leading coke producers. The United States has led the world in coke production since 1938 and in 1951 supplied 35 percent of total world production. Germany assumed temporary leadership in 1938, but war damages and territorial changes reduced production drastically for several ensuing years. However, production in the famous Ruhr area has been increasing steadily for several years, and production in Western Germany (Federal Republic) in 1951 ranked second only to the United States. Little reliable information has been available from

the Soviet Union since 1937, but estimates for 1951 place this country third in coke production. Reports made by competent engineers who have returned to the United States from Russia indicated that remarkable progress had been made in constructing modern coke and coal-chemical recovery plants. Other important coke-producing countries in 1951 were Great Britain, France (including the Saar), Poland, Belgium, and Czechoslovakia, which combined produced 22 percent of the world total.

COAL-CHEMICAL MATERIALS

GENERAL SUMMARY

Coal chemicals are derived from the vapors and gases recovered from the distillation of coal in slot-type coke ovens. The principal or basic chemical raw materials are gas, ammonia, crude light oil, and tar. The term "coal chemicals" also includes those fractions and individual compounds that are made from the basic materials by a chain of chemical processes. Coal chemicals are used by many industries and sometimes pass from one industry to another, as the product of one becomes the raw material for the other in the production of the final commodity. For this reason, a direct relationship exists between the coke industry and the countless others that depend entirely or partly upon coke ovens as a source of supply for essential chemical raw materials. Increased requirements of explosives, fertilizer materials, plastics, synthetic rubber and fibers, pharmaceuticals, paints, and waterproofing compounds, etc., for essential military and civilian purposes have proportionately increased the demand for ammonium sulfate, benzol, toluol, xylol, solvent naphtha, naphthalene, phenol, pyridine, picoline, and other coke-oven products entering into their manufacture. This, in turn, has prompted operators of slot-type ovens to place more emphasis on increasing the recovery of the basic chemical materials in order that larger quantities of refined or pure aromatic hydrocarbon products can be produced. New light-oil-refining and tar-processing equipment has been installed at various coke plants. At the end of 1951, obsolete equipment was being replaced by new construction in order that the coke-plant operators could produce coal chemicals to meet the most exacting specifications for plastics, synthetic rubber, explosives, and numerous other essential products. Ammonia recovery and processing systems were also being modernized and improved to produce a better grade of ammonium sulfate. Serious consideration was also given by a number of operating companies to the installation of new equipment and improved processes for the recovery of sodium phenolate, crude pyridine bases, and sulfur which in the past had not been economical to manufacture.

In spite of the best efforts of the coke producers in this field, however, the financial returns from the sale of all coal-chemical materials did not keep pace with the rise in coal costs nor the value assigned to the coke produced. The average cost of coal, per ton of oven coke

Digitized by Google

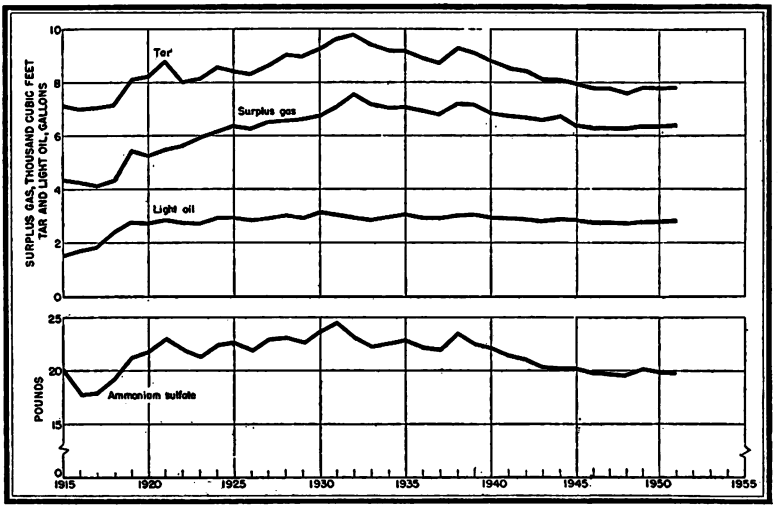

FIGURE 2.—Average yield of principal coal-chemical materials per net ton of coal carbonized in coke ovens, 1915–51. Yields of light-oil and ammonium sulfate equivalent represent average for plants recovering these products.

produced to oven-coke plant operators, increased 141 percent from 1937 to 1951, while the average value of oven coke produced increased 181 percent. Revenue from the sale of coal chemicals increased only 65 percent during the same period and in 1951 was equivalent to 24 percent of the total value of all products compared with 35 percent in 1937 (table 50). This reduction was due largely to the declining proportion of revenue received from the disposal of surplus gas, because the reported value of surplus gas in 1951 was equivalent to only 10 percent of the total value of all products, compared with 19 percent in 1937. These figures are arbitrary to the extent that the value assigned by some iron and steel companies to surplus gas used in their steelmaking furnaces is usually lower than the market price. The sale of surplus gas was still important to the merchant-coke plants in 1951, being responsible for about 20 percent of the total revenue derived from all products by this group. Should this important part of their revenue dollar be lost to competitive fuels, it might force more merchant plants out of business, in addition to those that had closed by 1951. Although prices on tar, ammonium sulfate, and light-oil derivatives have advanced, the gains made have not offset the decline in the percentage of revenue formerly accounted for by gas.

The increased quantity of coal-chemical materials produced, when coupled with modest gains in prices, resulted in the largest income ever reported from the sale of coal-chemical materials. The total received, $323.9 million, was $49.6 million (18 percent) higher than for the record year 1950.

COKE-OVEN GAS

After removal of the basic chemical raw materials (ammonia, tar, and crude light oil), coke-oven gas remains a potential source of chemicals, such as hydrogen, methane, ethylene, etc., but is not processed further for their recovery to any appreciable extent in the United States. About one-third of the gas recovered is used to heat the coke ovens, and the remainder (surplus gas) is used in integrated metallurgical operations as boiler fuel or distributed through city mains for public use.

Digitized by Google

Production of coke-oven gas totaled 1,052 billion cubic feet in 1951, a 7-percent increase over the 1950 output. The average unit value received for all surplus gas, whether used by producers or sold, declined slightly during 1951 to $0.212 per thousand cubic feet. The average value shown per thousand cubic feet for furnace plants was much lower than for merchant plants, as the latter include gas utilities. At coke plants integrated with iron and steel works, the bulk (88 percent) of the surplus gas was consumed within the works and was assigned a value in accordance with established accounting procedures. Gas utilities and, to a large extent, the merchant plants marketed the larger proportion of their gas production for residential and commercial use and thus realized a higher price. Merchant plants, including the coke plants operated by gas utilities, used only 12 percent of their surplus gas and sold 88 percent. Gas shown in table 53 as distributed through city mains was used principally for residential heating and cooking, although some part was undoubtedly used for industrial purposes.

CRUDE COAL TAR AND DERIVATIVES

Crude coal tar is recovered at all oven-coke plants, and production is therefore geared to oven operations. Output in 1951 increased 7 percent over the 1950 figure and was the highest ever attained in the United States. The yield of tar varies widely from plant to plant, depending on the kind of coal used, the temperature at which the ovens are operated, the degree of tar recovery, and other factors. In 1951 the average tar yield per ton of coal carbonized for individual plants ranged from 5.19 gallons to 10.88 and for the entire industry averaged 7.78 gallons, a slight decline from 1950. Coal tar has been used principally as a raw material in manufacturing numerous organic chemicals and as a fuel. Tar processing was begun as a separate industry in the United States at the very beginning of the oven-coke industry. The early tar-refining plants were operated independently of the coke ovens, although many were established near the ovens to be close to the source of supply. In the late 1920's, several coke-plant operators initiated the practice of processing part of their tar production. The practice expanded in the ensuing years as more plants installed tar-processing equipment. At some plants coal tar is only partly refined, or "topped." The topping operation is done

Digitized by Google

primarily to strip from the crude tar the low-boiling fraction (distillation range, usually under 300° C.), which is rich in tar acids, bases, and naphthalene. The distillate or crude chemical oil is sold to tar refiners for further processing. The residual tar or soft pitch is generally used by the producers as fuel. Of the 252.3 million gallons of crude tar processed in 1951 by coke-plant operators (32 percent of the total output), 59 percent was topped. The remainder was distilled at a higher temperature range to produce creosote oil. Crude tar sold to refiners totaled 424.1 million gallons—equivalent to 53 percent of the 1951 production and 5 percent more than the quantity so disposed of in 1950. Coke-oven tar represented approximately 95 percent of the total tar distilled or processed in the United States in 1951; the remainder consisted of low-temperature coal tar, retort-coal tar, and water- and oil-gas tar.

The use of crude tar as a fuel has declined in recent years, but considerable quantities are still burned. In 1951, 123.1 million gallons, or 15 percent of the production, was used for this purpose. Iron and steel companies operating coke ovens either burn or sell their crude tar, depending upon the economics involved. Merchant-coke plants, however, do not burn tar and, unless tar-processing facilities are available, must market their entire output.

The principal commercial tar products produced by coke-oven operators are creosote oil and crude chemical oil (tar-acid oil). Production of creosote oil, used mainly for wood preservation, increased 14 percent over 1950 and brought in 40 percent of the total revenue obtained from the sale of tar derivatives. Crude chemical oil contains naphthalene and tar acids and bases and usually is sold to tar refiners for further processing into phenol, cresols, xylenols, pyridine, naphthalene, and other pure products. Crude chemical oil production increased 41 percent over 1950 and represented 38 percent of the total value of tar derivatives sold. In processing tar, however, more pitch was derived than any other product; as most of the tar processing plants were at coke plants integrated with steel works, the pitch was usually burned, thus explaining the small volume of sales reported in table 49.

CRUDE LIGHT OIL AND DERIVATIVES

Crude light oil is the base from which benzol, toluol, xylol, etc., are made. The tremendous increase in the past decade in requirements of benzol for processing into styrene, phenol, aniline, nylon, etc., has emphasized the importance of this oil to our chemical industry. Crude light oil, when distilled fractionally, yields, roughly, 65 percent benzol. The yield of light oil varies from plant to plant, ranging from 1 to 4½ gallons per ton of coal carbonized, depending on the quality and kind of coal charged, the design and condition of the ovens, operating temperatures, and the type of scrubbing equipment. The average yield for the industry increased to 2.82 gallons in 1951, compared with 2.81 gallons in 1950.

Crude light oil is refined principally at coke-oven plants. In 1951, 270.5 million gallons (95 percent of the total output) was refined by the producers, and only 17.7 million gallons was sold for refining elsewhere. From the light oil refined, 234.3 million gallons (87 percent of the volume entering stills) was recovered in the form of salable products. The yields of products obtained from refining operations are given in table 57.

In the early days of the industry, the usual practice was to include as light oil all materials distilling up to 200° C. However, in modern benzol-refining plants, a secondary fraction is separated between 150° and 200°. This secondary fraction, known as "intermediate light oil," contains about 50 percent of polymerizable material, coumarone, indene, and dicyclopentadiene. The remainder is mainly polyalkylbenzenes and naphthalene. The intermediate light oil is generally sold by the coke-plant operators for the recovery of coumarone-indene resins, solvents, shingle-stain oils, etc. Production of intermediate light oil in 1951 amounted to 845,270 gallons, a slight decline from the 1950 figure.

Benzol production from coke-oven operations reached an alltime peak in 1951, when 178.0 million gallons of all grades was recovered. Specification or chemical grades (1°, 2°, and 90 percent) amounted to 172.8 million gallons and motor grade, 5.1 million gallons; however, the latter classification is somewhat misleading because only a small quantity of benzol was actually used as automotive fuel in 1951, the greater part of this grade being sold for further processing into the purer or chemical grades. Requirements for chemical grades of benzol exceeded the supply from domestic raw materials, and 68,539,583 gallons of crude and motor grade was imported for refining into the chemical grades. Production of benzol from petroleum also increased substantially and amounted to 12 percent of the total United States production of the chemical grades from all sources. The price of coke-oven benzol, which was limited by ceiling prices established by the Office of Price Stabilization, averaged $0.34 per gallon for 1951.

Toluol is another light-oil derivative having many important applications in the chemical field. It is used extensively as a solvent, particularly in the manufacture of synthetic plastics, and also for synthesizing a number of chemicals, such as benzoic acid. In wartime toluol is important in manufacturing explosives and for enriching aviation gasoline. Unlike benzol, which in the past has been made almost entirely from coal, the production of toluol from petroleum was begun on a large scale during World War II. In 1951 coke-oven operators produced 34 percent of the United States total of toluol.

Xylol is also an aromatic material being made from petroleum in increasing quantities. Coke-plant operators produced only 11 percent of the national total in 1951. Prices on all toluol, xylol, and other light oil derivatives were under price ceilings.

NAPHTHALENE

Crude naphthalene has become one of the most important basic raw materials of the aromatic-chemical industry because of the large number of essential products made from it. Its principal derivative is phthalic anhydride, used in the production of smokeless powder, alkyd paint resins, dyestuffs, insecticides, etc. Naphthalene is recovered at coke plants from the refining of crude light oil or tar and to a smaller extent from the final coolers. The commercial grades of crude naphthalene are defined in terms of melting points. Crude grades ranging from 74° to 79° are suitable for some industrial uses without further refining. Crude below 74° C. has virtually no direct commercial use and is sold by the coke-plant operators to tar refiners

Digitized by Google

for upgrading or refining. It is estimated that about 60 percent of the total amount of naphthalene recovered at coke plants in 1951 was less than 74° C. The production of all crude grades (below 79° C.) in 1951 totaled 125.6 million pounds, an increase of 26 percent over the 1950 output. Production of naphthalene at coke plants was expected to increase substantially upon completion of new facilities for its recovery from coke-oven tar being constructed at some operations.

COKE-OVEN AMMONIA

Ammonia is recovered at coke plants, either in water solution (ammonia liquor) or as a crystallized ammonium sulfate. In 1951, of the 84 active oven-coke plants, 80 recovered ammonia, 65 ammonium sulfate, and 17 ammonia liquor (2 plants produced sulfate and liquor). Usually 85 to 90 percent of the ammonia recovered from the ovens is converted into a sulfate, which is used almost exclusively for agricultural purposes. However, the merchant-coke plants recover a larger proportion of the ammonia in the form of liquor, and this group of plants produced 63 percent of the total liquor output in 1951. Ammonia liquor produced by coke-plant operators is employed for chemical and agricultural purposes. Although data are not available on the quantity of ammonia liquor used for each purpose, it is estimated that over half has been used industrially in the manufacture of soda ash, ammonium chloride, and sulfuric acid. Until recent years, coke ovens furnished the bulk of the ammonium sulfate consumed in the United States. However, a few producers have constructed large synthetic ammonia plants to produce ammonium sulfate; as a result, about half of the 1951 United States production of ammonium sulfate was made from synthetic ammonia.

COKE OVENS OWNED BY CITY GAS COMPANIES (PUBLIC UTILITIES)

Table 61 compares the operation of coke plants owned by gas utilities with those not so owned and is presented by the Bureau of Mines for the information of those interested in the coking activities of public utility plants. The development of slot-type coke ovens in the United States during the early part of the twentieth century and the adaptability of such ovens to the manufacture of city gas induced a number of utilities to install slot-type coke ovens to supplement or even replace coal-gas retorts. The number of coke plants operated by city gas companies reached a peak in 1934, when 23 such plants were active. In that year, gas utility plants produced 11 percent of the total United States oven-coke output, 12 percent of the coke-oven gas and tar, 9 percent of the coke-oven ammonia, and 4 percent of the crude light oil. However, development of long-distance pipelines has brought natural gas into many areas formerly served by coke-oven gas. This has resulted in the sale or retirement of some plants by the utilities. In 1951, the Niagara Mohawk Power Corp. permanently closed its plant at Utica, N. Y., and sold its Troy, N. Y., plant to the Republic Steel Corp. This action reduced the number of plants operated by gas utilities at the end of the year to nine. Several other companies were planning to substitute natural gas for coke-oven gas in 1952 and would close their coke plants unless they could be disposed of to other interests.

Economical operation of a coke plant requires a properly balanced market under favorable conditions for all products, since production of any one is almost invariably accompanied by production of all the others. Therefore, loss of a market for coke-oven gas makes it difficult for a city gas plant to operate profitably. Revenue from sales of surplus gas from these plants constituted 26 percent of the total revenue obtained from all products. City gas plants in 1951 contributed 5 percent of the total production of oven coke, gas, and tar; 3 percent of the crude light oil; and 4 percent of the ammonia.

Copper

By Helena M. Meyer and Gertrude N. Greenspoon

GENERAL SUMMARY

EFFORTS of both Government and industry in 1951 were directed toward meeting the expanded United States demand for copper that resulted chiefly from the accelerated defense program; in the absence of success in this endeavor, the Government extended inventory, use, and other controls, inaugurated in late 1950. Provision had to be made also for further expansion in consumption in 1952, when the defense program was expected to attain still higher levels.

Despite all efforts to increase supplies, the copper made available for use in 1951 fell slightly below the total for 1950. Domestic mine output and smelter and refinery production from domestic crude primary materials were 2 to 3 percent above 1950 and the largest since 1944. Output of copper as refined copper and in alloys from old scrap, however, declined 6 percent from 1950. The 29-percent drop in receipts of copper from abroad, in the form of both refined and unrefined copper, to the lowest level since 1947 was the principal reason that supplies in 1951 were smaller than in 1950. A further cause was the low level of producers' stocks of refined metal on January 1, when they were smaller than at any time since 1906 and not only were too low for operating efficiency to be drawn upon further, but needed replenishment to a more practicable working tonnage. A 35-percent increase was made in such stocks in 1951, but otherwise they remained the smallest since 1906.

Mine output rose slightly in 1951 despite labor strikes. Production came within 20,000 to 25,000 tons of what may be considered the maximum practicable tonnage under the conditions of available labor and capacity prevailing in that year. The almost month-long strike at the American Smelting & Refining Co. smelter at Garfield, Utah, in July interrupted the smelting of concentrates from the Utah Copper mine, Bingham, Utah, the largest copper producer in the United States, but in the end may have merely delayed this copper in reaching its market. The widespread strike of mine, mill, and smelter workers (beginning in late August and ending about a week later when an 80-day Taft-Hartley national emergency injunction was invoked) adversely affected operations in all major copper-producing States. Smelter and refinery losses due to strikes were even greater, although some of the loss was made up, and some stored crude materials may have contributed to slightly higher smelter and refinery outputs early in 1952 than would otherwise have been possible.

The crisis caused by the loss in mine and plant production led to unprecedented release of 25,000 tons of copper from the United States National Stockpile in August and a subsequent authorization, October 1, for release of an additional 30,000 tons. The stockpile was to be reimbursed in metal for these withdrawals.

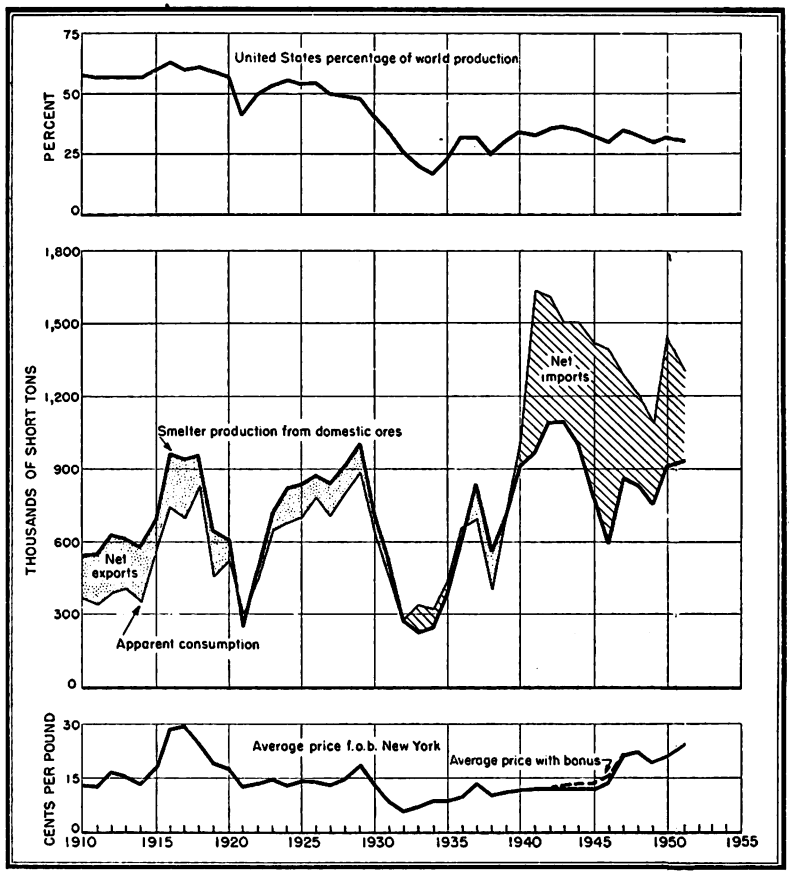

FIGURE 1.—Production, consumption, and price of copper in the United States, 1910–51.

Continuation of Government efforts to assure adequate supplies of copper and other materials for military requirements and to prevent—insofar as possible—dislocation of the industrial economy, was made possible by extension of the Defense Production Act. Under this act the Defense Minerals Administration in the Interior Department and its successor, the Defense Materials Procurement Agency, continued efforts to expand output. Copper production, however, does not lend itself to rapid expansion. To solve the immediate problem of filling expanding military and continuing large industrial requirements with static or reduced supplies, the National Production Authority reinstituted the Controlled Materials Plan, used effectively in World War II, for copper, steel, and aluminum, the three materials covered by that major war device of the earlier period. On July 13 the NPA announced that copper raw materials would be placed under complete allocation control, effective August 1.

Copper was one of the commodities for which ceiling prices were established by the General Ceiling Price Regulation, effective January

Digitized by Google

26. This order set maximum prices at not to exceed the highest prices received by individual producers between December 19, 1950, and January 25, 1951, inclusive. Primary producers in general had been selling electrolytic copper, delivered Connecticut Valley, at 24½ cents a pound; as a consequence, that figure became their ceiling price. There were, however, companies whose ceiling prices substantially exceeded the 24½-cent figure. The quantities to which higher ceilings applied were relatively small.

The Office of Price Stabilization announced that, effective July 25, the ceiling price for copper refined in the United States from imported crude materials was 27½ cents a pound delivered Connecticut Valley. The increased cost of foreign copper was not to be passed on to customers by the fabricators.

Trading in copper, lead, and zinc on the Commodity Exchange was terminated July 27.

The average quoted price for copper in 1951 was reported as 24½ cents a pound for electrolytic copper, delivered Connecticut Valley, and was higher than in any year since 1918. It would appear logical to assume that this price would encourage domestic production, despite increased costs since 1918. The high level of excess profits taxes in recent years, however, would tend to have the opposite effect. Response of copper production to price stimulation, in addition, is always slow because of the large capital expenditures required to bring new capacity into operation. Moreover, production would not increase, but decrease, if higher prices made lower grade material economic and unless excess mill capacity were available at properties mining such lower grade ores. If the quoted copper price is adjusted according to variations in the Bureau of Labor Statistics wholesale price index, however, the 1951 price is found to be below prices in 1947, 1940, 1939, 1937, and in most years from 1922–30, inclusive.

Rising costs threatened some loss of output from high-cost mines. In December the DMPA moved to prevent such losses by offering to negotiate over-the-ceiling contracts with high-cost mines then in actual production. Nine properties were involved in such negotiations at the end of the year.

Inability to increase imports in 1951, or even to maintain them at 1950 levels, was a major disappointment to defense officials trying to stretch supplies to meet expanding needs. Total imports, including scrap, for the year fell 29 percent, the unrefined classes—ores, matte, and blister—dropping 27 percent and the refined class 25 percent; scrap receipts fell 86 percent. All of the chief suppliers in 1950 sent smaller quantities to the United States in 1951: Canada dropped 34 percent, Mexico 24 percent, Chile 8 percent, and Peru 65 percent. Receipts of unrefined copper from Northern Rhodesia were halved, and the unusual imports of refined copper from Japan in 1950 were virtually discontinued in 1951.

Exports of refined copper in 1951 were substantially less than the relatively low rates of recent years.

An agreement between the United States and Chilean Governments in May 1951 provided for payment of an additional 3 cents a pound over the ceiling for Chilean copper sold in the United States. The agreement called for expansion in Chile's production and for Chile's discontinuance of abnormal trade in semiprocessed copper, by restrict-

Digitized by Google

ing to not more than 20 percent the withholding by Chile of production of American companies operating in Chile and providing for a Chilean embargo on exportation of copper to countries of the Soviet bloc.

The 2-cent copper excise tax was suspended from April 1, 1951, to February 15, 1953, or to termination of the national emergency, whichever is first, by a law signed by the President in May.

Partly because of expanded defense mobilization, world demand in 1951 was at a sharply accelerated rate, and world prices soared. Trustworthy information on prices for copper sold outside the United States, however, is not available. Press statements have called attention to fantastically high prices prevailing in foreign countries. It is known that such prices were paid, but there are no data to show what quantities were involved. There is little doubt, however, that the United States, because of ceiling price restrictions, contrasted with uncontrolled markets on the European Continent, was at a disadvantage in seeking foreign copper. This condition offset in part the longtime advantage resulting from the desire of foreign countries to obtain United States dollars.

TABLE 1.—Salient statistics of the copper industry in the United States, 1942–46 (average) and 1947–51, in short tons

	1942–46 (average)	1947	1948	1949	1950	1951
New (primary) copper produced—						
From domestic ores, as reported by—						
Mines	905,012	847,563	834,813	752,750	909,343	928,330
Ore produced:

Smelters	913,338	862,872	842,477	757,931	911,352	930,774
Percent of world total	34	34	32	29	31	30
Refineries	894,978	909,213	860,022	695,015	920,748	951,559
From foreign ores, matte, etc., refinery reports	305,477	250,757	247,424	232,912	319,086	255,429
Total new refined, domestic and foreign	1,200,455	1,159,970	1,107,446	927,927	1,239,834	1,206,988
Secondary copper recovered from old scrap only	442,980	503,376	505,464	383,548	485,211	458,124
Imports (unmanufactured) [2]	703,155	413,890	507,449	552,709	[3] 690,389	489,376
Refined	396,466	149,478	249,124	275,811	[3] 317,363	238,547
Exports of metallic copper [4]	194,513	196,999	207,022	195,990	192,339	166,274
Refined (ingots and bars)	95,366	147,642	142,598	137,827	144,561	133,305
Stocks at end of year (producers)	366,400	273,000	250,000	322,000	258,000	217,000
Refined copper	91,900	60,000	67,000	61,000	26,000	35,000
Blister and materials in solution	274,500	213,000	183,000	261,000	232,000	182,000
Withdrawals (apparent) from total supply on domestic account:						
Total new copper	1,484,000	1,286,000	1,214,000	1,072,000	1,447,000	1,303,000
Total new and old copper (old scrap only)	1,927,000	1,789,000	1,719,000	1,456,000	1,932,000	1,761,000
Price average [5] cents per pound	12.3	20.9	21.7	19.7	20.8	[6] 24.2
World smelter production, new copper	2,688,000	2,513,000	2,623,000	2,640,000	[3] 2,960,000	3,142,000

[1] Includes old tailings smelted or re-treated. Not comparable with mine production figure shown in that latter includes recoverable copper content of ores not classified as "copper."

[2] Data are "general" imports; that is, they include copper imported for immediate consumption plus material entering country under bond. Comprises copper in ingots, plates, and bars, ores and concentrates, regulus, blister, and scrap.

[3] Revised figure.

[4] Total exports of copper, exclusive of ore, concentrates, composition metal, and unrefined copper. Exclusive also of "Other manufactures of copper," for which quantity figures are not recorded. (See table 26.)

[5] Exclusive of bonus payments of the Office of Metals Reserve under Premium Price Plan, which covered the period February 1, 1942, to June 30, 1947, inclusive.

[6] Exclusive of copper produced abroad and delivered in the United States.

The price for electrolytic copper in the United Kingdom was increased in April to the equivalent of 26.25 cents a pound, then in May to the equivalent of 29.25 cents, but subsequently dropped in September to 28.37½ cents where it held for the remainder of the year.

The world shortage of copper in 1951 led to placing copper under international allocation (Free World countries). Quotas were established by the International Materials Conference for the fourth quarter of 1951. The member countries voluntarily accepted restrictions upon quantities to be consumed, but no attempt was made to regulate prices or to interfere otherwise with distribution or with competition for preferred sources of supply. Chile insisted on the right to withhold from international agreement the copper retained by that Government under agreement with the United States State Department, already mentioned. Member countries agreed not to dispose of copper to countries in the Soviet bloc.

Expansion of Production Under the Defense Production Act.—A number of properties were certified in 1951 for Government assistance, under provisions of the Defense Production Act, for expansion of copper output at mines now operating or idle or for maintenance of production that might be lost without such aid. The properties were to receive Government loans, Government purchase contracts, or tax-amortization benefits, or combinations of the three types of assistance. The most important projects are outlined in the following paragraphs. Not yet approved but in an advanced stage of negotiation was the San Manuel project, Arizona.

The Government loan ($7,500,000) obtained by the Copper Cities Mining Co., Arizona, a subsidiary of the Miami Copper Co., was mentioned in the Copper chapter of Minerals Yearbook, 1950. A purchase agreement was obtained by the company under which the company may call on the Government to purchase, at 23 cents a pound (subject to escalation), a maximum of 85,000 tons out of the first 96,250 tons produced if it is unable to dispose of the tonnage at the same or higher prices. Production from the mine was scheduled to begin in the latter part of 1954. This would allow about 1 year to move the Castle Dome plant and mining equipment and reerect it at the new location at Copper Cities following conclusion of the Castle Dome operation.

On November 15 a loan of $57,185,000 was authorized to the White Pine Copper Co., Michigan, a new, wholly owned subsidiary of the Copper Range Co., by the Reconstruction Finance Corporation. The Defense Production Administration certified for accelerated amortization this project and certified a copper program which included provision for a contract with the Government for production by the company of an estimated 275,000 short tons of refined copper.

The Anaconda Copper Mining Co. entered into a contract with the Government under which the oxide ore body of the Yerington mine, Lyon County, Nev., was to be brought into production. The Government was to buy at not less than 25.5 cents a pound any copper that the company could not sell to industrial users at that minimum, up to a maximum of 128,000 tons during the first 6 years of operation. The ore body was said to contain approximately 35 million tons of oxide ore having a grade of 0.97 percent copper, which could be mined by open-pit methods; under it lies at least 15 million tons of sulfide ore of similar grade. Open-pit mining was expected to start in late 1953

Digitized by Google

at a rate of 30,000 tons a year, which was to be increased to an annual rate of 33,000 tons by 1955. The company acquired the Leviathan sulfur mine in Alpine County, Calif., as a source of the sulfuric acid required for leaching the oxide ores. Preparatory expenditures at Yerington and Leviathan were expected to approximate $38 million. The company was to finance this expenditure but was granted Certificates of Necessity permitting accelerated amortization for income-tax purposes of 75 percent of the amortizable portion of these expenditures over a 5-year period.

The American Smelting & Refining Co. entered into an agreement with the Government under which the company was to finance an estimated expenditure of $17 million to bring the Silver Bell unit, 40 miles northwest of Tucson, Ariz., into production. A Certificate of Necessity was also obtained. The ore reserves were estimated at 32 million tons assaying approximately 0.9 percent copper, in 2 separate ore bodies, which could be mined by open-pit methods. The Government was to purchase 88,500 tons of the first 98,500 tons produced at 24½ cents a pound, subject to adjustments for operating costs, provided this quantity could not be sold at that price or more in the open market. The Government was to be obligated for 5½ years from commencement of operations. Stripping of the ore body was begun in December 1951, and estimated production was to be at the rate of 18,130 tons annually. The property was expected to be in operation early in 1954, barring unforeseen delays.

The Government entered into a contract with the Phelps Dodge Corp. for copper from the Bisbee East ore body (Lavender pit), Arizona, mentioned in the Copper chapter of Minerals Yearbook, 1950. The corporation was to bear the entire cost of developing and equipping the property and of installing the necessary plant, such cost estimated at about $25 million. The corporation was given the right, under the contract, to call on the Government to purchase up to 112,500 short tons of copper out of the first 150,000 tons at 22 cents a pound, with an escalation clause, and the Government could purchase any part of the 150,000 tons at the floor price or the market price, whichever was higher. A Certificate of Necessity was also obtained. Barring unforeseen equipment and manpower problems, production should begin by the end of 1954. Estimates were that 38,000 tons a year would be produced annually for 11 or 12 years.

The Kennecott Copper Corp. undertook to prepare for production an undeveloped ore body near the corporation's existing open-pit operation at Ruth, Nev., known as the "Deep Ruth." It was to be an underground mine and was expected by the company to yield only a small margin of profit, based on 1951 price-cost relationship. The corporation received a Certificate of Necessity, permitting the chargeoff, over a 5-year period, of the portion of the cost allowed by the Bureau of Internal Revenue. No Government loan or purchase contract was requested. The ore averages 0.83 percent copper.

The corporation had explored and was preparing for development another, smaller ore body, known as the "Veteran," which lies 1½ miles from the Ruth open pit. The ore in this deposit averages 0.9 percent copper and could be mined by open-pit methods.

Bureau of Mines Reports.—The following Bureau of Mines reports of investigations, published recently, relate to copper in whole or in part.

4828. Investigation of Kasna Creek Copper Prospect, Lake Kontrashibuna, Lake Clark Region, Alaska.
4850. Copper Giant Deposits, Pima County, Ariz.
4860. Diamond Drilling at Torpedo Copper Mine, Organ Mining District, Dona Ana County, N. Mex.

The following Bureau of Mines information circulars likewise discussed copper.

7602. Mines and Mineral Deposits (Except Fuels), Judith Basin County, Mont.
7612. Safety in Hoisting at the United Verde Mine, Phelps Dodge Corp., Jerome, Ariz.
7623. Safety in Milling: Magma Copper Co., Superior, Ariz.
7626. Two-Way Radio Communication at Santa Rita Open Pit, Kennecott Copper Corp., Santa Rita, N. Mex.

DOMESTIC PRODUCTION

Statistics on copper production may be compiled upon a mine, smelter, or refinery basis. Mine data are most accurate for showing the geographic distribution of production; smelter figures are better than mine figures for showing the actual recovery of metal and more accurate than refinery figures for showing the source of production; and refinery statistics are best for showing recovery of metal but indicate only in a general way the source of crude materials treated. Mineral Resources of the United States, 1930, part I (pp. 701–702), discusses differences among the three sets of figures.

TABLE 2.—Copper produced from domestic ores, as reported by mines, smelters, and refineries, 1947–51, in short tons

Year	Mine [1]	Smelter	Refinery
1947	847,563	862,872	909,213
1948	834,813	842,477	860,022
1949	752,750	757,931	695,015
1950	909,343	911,352	920,748
1951	928,330	930,774	951,559

[1] Includes Alaska.

PRIMARY COPPER

Mine Production.—The figures for mine production are tabulated from reports supplied by all domestic mines that produce copper. These data are classified geographically, by metallurgical method, and by type of ore. Tables presenting the information in detail are to be found in the State chapters of this volume.

As usual, Arizona led all other States by a wide margin in production in 1951, supplying 45 percent of the total for the United States, followed by Utah, with 29 percent. Arizona's output comes from a number of important copper-producing districts and mines, whereas Utah's is predominantly from one mine, the largest copper producer in the United States. Production from New Mexico, Montana, Nevada, and Michigan, ranking next in importance as copper producers in 1951, made up 23 percent of the total. These 6 States produced 97 percent of the United States total.

Classification of production by mining method showed that approximately 74 percent of the recoverable copper and 84 percent of the copper ore came from open pits in 1951. Most of the domestic copper ore was treated by flotation at or very near the mine of origin, and the resulting concentrates were shipped for smelting. Some copper ores were leached, and some were direct smelted either because of their high grade or because of their fluxing qualities.

The first 5 mines in table 6 produced 65 percent of the United States total, the first 10 produced 84 percent, and the entire 25 furnished 98 percent.

Quantity and Estimated Recoverable Content of Copper-Bearing Ores.—Tables 7 through 10 list the quantity and estimated recoverable copper content of the ore produced by copper mines in the United States in 1951. Of the total copper produced from copper ores in the United States during 1951 (1950 data in parentheses), 93 (94) percent was obtained from ores concentrated before smelting, 3 (2) percent from direct-smelting ores, and 4 (4) percent from ore treated by straight leaching.

Close agreement between the output as reported by smelters and the recoverable quantity as reported by mines indicates that estimated recoverable tenor is close to actual recovery. Classification of some of the complex western ores is difficult and more or less arbitrary. "Copper ores" include not only all those that contain 2.5 percent or more recoverable copper but also those that contain less than this percentage if they are valuable chiefly for copper, notably the "porphyry ores." Mines report considerable copper from ores mined primarily for other products. These include siliceous gold and silver ores, lead and zinc ores, and pyritic ores.

TABLE 7.—Copper ore, old tailings, etc., sold or treated in the United States in 1951, with copper, gold, and silver content in terms of recoverable metal [1]

State	Ore, old tailings, etc., sold or treated (short tons)	Recoverable metal content				Value of gold and silver per ton of ore

Smelter Production.—The recovery of copper by smelters in the United States from ores of domestic origin totaled 930,774 short tons in 1951, a 2-percent increase from the 911,352 tons for 1950. Output of United States smelters from domestic ores constituted 30 percent of the world production for 1951 compared with 31 percent in 1950. (*See also* fig. 1.)

The figures for smelter production shown in table 11 are based upon returns from all primary smelters handling copper-bearing materials

TABLE 11.—Copper produced (smelter output from domestic ores) in the United States, 1942–46 (average) and 1947–51, and total, 1845–1951

Year	Short tons	Value [1] (thousands of dollars)
1942–46 (average)	913,338	221,784
1947	862,872	360,680
1948	842,477	365,635
1949	757,931	298,625
1950	911,352	379,122
1951	930,774	450,495
Total 1845-1951	37,336,647	11,443,491

[1] Excludes bonus payments of Office of Metals Reserve under Premium Price Plan in effect Feb. 1, 1942, to June 30, 1947.

produced in the United States. Blister copper is accounted for in terms of fine-copper content. Some casting and electrolytic copper produced direct from ore or matte is included in the smelter production, as well as in the refinery output. For Michigan. furnace-refined copper is included. Metallic and cement copper recovered by leaching is included in smelter production.

The quantity and value of copper produced from domestic ores by smelters in the United States are shown by years for 1845–1930 in Mineral Resources of the United States, 1930, part I (p. 703).

TABLE 12.—Primary and secondary copper produced by primary refineries in the United States, 1942–46 (average) and 1947–51, in short tons

	1942–46 (average)	1947	1948	1949	1950	1951
Primary:

Refinery Production.—The refinery output of primary copper in the United States in 1951 was made by the same 13 plants that supplied the 1950 production (*see* Copper chapter of Minerals Yearbook 1950, pp. 478, 479). The electrolytic plants produced at 78 percent of capacity in 1951 compared with 84 percent in 1950.

Tables 12 and 13 show the production of refined copper at primary refining plants, classified according to source of copper, grade, and form in which cast.

TABLE 13.—Copper cast in forms at primary refineries in the United States, 1949–51

Form	1949		1950		1951	
	Thousands of short tons	Percent	Thousands of short tons	Percent	Thousands of short tons	Percent
Wire bars	665	59	799	56	774	58
Cathodes	128	11	189	13	146	11
Ingots and ingot bars	117	10	111	8	142	11
Billets	108	10	172	12	141	10
Cakes	106	9	130	9	119	9
Other forms	16	1	29	2	20	1
Total	1,140	100	1,430	100	1,342	100

In addition to the primary refineries, many plants throughout the country operate on scrap exclusively, producing metallic copper and a variety of alloys. The output of these plants is not included in the statements of refined-copper production in tables 12 and 13 but is included in table 15 on secondary-copper production.

Copper Sulfate.—Production and shipments of copper sulfate in 1951 were greater than in 1950. Shipments were less than production in 1951, and stocks at the end of the year were more than double those at the end of 1950. Of the total shipments of 104,260 tons, producers' reports indicated that 43,960 tons was for agriculture, 27 008 tons for industrial, and 33,292 tons for other uses.

TABLE 14.—Production, shipments and stocks of copper sulfate in 1947–51, in short tons

Year	Production		Shipments (gross weight)	Stocks at end of year [1] (gross weight)
	Gross weight	Copper content		
1947	89,100	22,276	86,600	10,200
1948	96,700	24,186	93,100	11,800
1949	79,000	19,749	84,400	6,400
1950	87,300	21,814	91,300	2,200
1951	106,944	26,736	104,260	4,888

[1] Some small quantities are purchased and used by producing companies, so that the figures given do not balance exactly.

A booklet published recently contained considerable data on uses of copper sulfate.[1]

SECONDARY COPPER

Copper recovered from copper scrap, copper-alloy scrap, and other copper-bearing scrap materials, as metal, as copper alloys without separation of the copper, or as copper compounds, is known as secondary copper. Quantities are reported in terms of copper content.

Secondary copper is produced from new and from old scrap. "New scrap" is defined as refuse produced during the manufacture of copper articles and includes defective finished or semifinished articles that must be reworked. Typical examples of new scrap are defective castings, clippings, punchings, turnings, borings, skimmings, drosses, and slag. "Old scrap" consists of metal articles that have been discarded after having been used. Such articles may be worn out, obsolete, or damaged. Typical examples are discarded trolley wire, fired cartridge cases, used pipe, and lithographers' plates.

Table 15 summarizes the production of secondary copper during 1942–51. Refined copper produced from scrap at primary refineries is included in the "unalloyed" class. Detailed information appears in the Secondary Metals—Nonferrous chapter of this volume.

TABLE 15.—Secondary copper produced in the United States, 1942–46 (average) and 1947–51, in short tons

	1942–46 (average)	1947	1948	1949	1950	1951
Copper recovered as unalloyed copper	120,886	303,092	284,026	250,089	260,704	186,462
Copper recovered in alloys [1]	834,075	658,649	688,762	463,054	716,535	745,820
Total secondary copper	954,961	961,741	972,788	713,143	977,239	932,282

[1] Includes copper in chemicals, as follows: 1942–46 (average), 16,338; 1947, 18,838; 1948, 17,612; 1949, 14,840; 1950, 17,413; 1951, 22,905.

CONSUMPTION

Apparent consumption of primary copper, which includes copper shipped to the National Stockpile, dropped 10 percent from the peacetime peak established in 1950, although demand was greater, and chiefly because less metal was obtained from abroad. Figures on apparent consumption, as well as the derivation of these figures, are shown in table 16; data for a long period are available on this basis. In estimating apparent consumption, it has been assumed that copper used in primary fabrication of copper is consumed. Although the table aims to show primary consumption only, it should be noted that exports and stocks, as well as the import component of "total supply," include some refined secondary copper that cannot be determined separately. Actual consumption of new copper would also differ from the figures shown in the table by changes in consumers' stocks. The figures on apparent consumption in 1947 and 1948 are especially distorted by the fact that during this period unusual quantities of copper were imported as scrap and reexported in refined form. Because refined exports cannot be broken down to show new and old copper,

Apparent withdrawals on domestic account [3]	1,286,000	[4] 1,214,000	[4] 1,072,000	[4] 1,447,000	[4] 1,303,000

[1] May include some copper refined from scrap.
[2] Revised figure.
[3] Adjusted for Office of Metals Reserve stock changes; OMR stocks consigned to National Stockpile late in 1948.
[4] Includes copper delivered by industry to the National Stockpile.

these reexports were necessarily deducted from apparent consumption, even though the scrap from which they were produced was not included in available supply.

The Bureau of Mines began to compile figures on actual consumption of refined copper in 1945. Details for 1949 to 1951, inclusive, are shown in table 17. Unlike table 16, in which all but new copper is eliminated so far as possible, table 17 does not distinguish between new and old copper but covers all copper consumed in refined form.

TABLE 17.—Refined copper consumed in 1949–51, by class of consumer, in short tons

Class of consumer	Cathodes	Wire bars	Ingots and ingot bars	Cakes and slabs	Billets	Other	Total
1949:							
Wire mills	19	605,430	18,230			34	623,713

Digitized by Google

Consumption by wire mills was notably higher in the period 1947 to 1951, compared with 1945 and 1946. In the latest 5-year period wire mills have regularly taken over half of the total refined copper used.

STOCKS

Producers' stocks of refined and unrefined copper declined 16 percent in 1951 and were the smallest since 1915. Year-end inventories of refined copper, however, rose over the low of 1950 but except for 1950 were the smallest since 1906. Only 16 percent of the total at the end of 1951 was in the form of refined copper, the remainder being in smelter shapes at smelters and in transit to refineries, and in smelter shapes and materials in process of refining at refineries. Table 18 gives stocks of copper including smelted and refined material of foreign and scrap origin as reported by primary smelting and refining plants.

TABLE 18.—Stocks of copper at primary smelting and refining plants in the United States at end of year, 1946–51, in short tons

Year	Refined copper [1]	Blister and materials in process of refining [2]	Year	Refined copper [1]	Blister and materials in process of refining [2]
1946	96,000	254,000	1949	61,000	261,000
1947	60,000	213,000	1950	26,000	232,000
1948	67,000	183,000	1951	35,000	182,000

[1] May include some copper refined from scrap.
[2] Includes copper in transit from smelters in the United States to refineries therein.

Fabricators' stocks of refined metal (including in-process copper and primary fabricated shapes), according to the United States Copper Association, were 280,402 tons at the end of 1951 or 3 percent less than at the beginning of the year, continuing the downtrend since 1947. Working stocks (see table 19) were 295,385 tons, or 2 percent more than those at the end of 1950. After unfilled sales of metal are accounted for, the deficiencies in stocks in relation to unfilled orders rose 67,055 tons to 285,886 tons at the end of 1951. The latter figure represented the largest deficiency since the end of 1946.

TABLE 19.—Stocks of copper in fabricators' hands at end of year, 1947–51, in short tons

[U. S. Copper Association]

	Stocks of refined copper [1]	Unfilled purchases of refined copper from producers	Working stocks	Unfilled sales to customers	Excess stocks over orders booked [2]
	(1)	(2)	(3)	(4)	(5)
1947	423,432	103,765	293,859	338,260	−104,922

Digitized by Google

Figures compiled by the Copper Institute show that domestic stocks of refined copper increased from 49,040 tons at the end of 1950 to 71,528 tons at the end of 1951. Inventory data of the Bureau of Mines and the Copper Institute always differ owing to somewhat different bases. Before 1947 a primary reason was that the Copper Institute coverage was limited to duty-free copper. Inclusion by the Copper Institute of all copper after January 1, 1947, reduced the differences chiefly to variations in interpretation. In the Bureau of Mines classification, cathodes to be used chiefly for casting into shapes are considered stocks in process and not refined stocks.

PRICES

Reports to the Bureau of Mines from copper-selling agencies indicated that 998,000 tons of domestic refined copper was delivered to purchasers in 1951, at an average price (f. o. b. refinery, except for that part sold by the Kennecott Sales Corp., whose sales are on the basis of copper delivered to consumers' plants) of 24.2 cents a pound. This figure is not comparable to data for earlier years, which included deliveries of foreign copper to United States buyers. After the first part of May Chilean copper was sold for 3 cents a pound more than the domestic ceiling price (*see* Summary section of this chapter), and beginning July 25 the ceiling price for copper refined in the United States from imported crude materials was raised 3 cents. The average price for foreign copper delivered in the United States in 1951, including that sold before the agreement with Chile in May, was 26.2 cents a pound. The average for the foregoing classes together was 24.7 cents a pound, which may be compared with the price of 20.8 cents for copper delivered in 1950.

The General Ceiling Price Regulation is discussed in the opening section of this chapter. Quoted prices for domestic electrolytic copper, delivered Connecticut Valley, continued at 24.5 cents a pound throughout the year.

The excise tax on copper, which was reinstituted July 1, 1950, was again suspended effective April 1, 1951. (*See* section on Foreign Trade—Tariff of this chapter.)

The quoted price for export copper, f. o. b. refinery, was approximately 0.225 cent a pound above the domestic quotation until May, when the price for Chilean copper was raised. From June the differential was 3.225 cents a pound for the remainder of the year.

Trading in copper, lead, and zinc on the Commodity Exchange was terminated July 27, as a result of certain effects of the general price-ceiling regulation and upon virtual liquidation of outstanding contracts.

London Price.—The official maximum price of the British Ministry of Supply was £202 per long ton (equivalent to 25.25 cents a pound) when the year began and was increased £8 to £210 (26.25 cents) in April and another £24 to £234 (29.25 cents), the highest sterling price on record, in May. The drop of £7 to £227 (28.375 cents) in September was announced by the British Ministry of Materials, which took over metal-purchasing functions from the Ministry of Supply in July. There were no further changes before the end of the year.

FOREIGN TRADE [2]

Imports of copper in 1951 dropped sharply from 1950 levels despite increasing United States requirements for the metal. Meanwhile exports continued subject to export control and were below the reduced rates of other recent years. Before World War II the United States generally produced more than enough copper for its own needs and had a surplus available for export. In 1920 to 1939, for example, 6,500,000 tons of copper was exported in refined shapes, whereas refined copper produced from imported crude primary materials and imports of refined copper together amounted to 5,800,000 tons. The relationship between imports and exports for 1920 to 1939 by no means gives the complete story, because much of the copper exported cannot be measured quantitatively, being in such end items as electric motors, automobiles, and equipment of various types.

For years the excess capacity of domestic smelting and refining facilities was used to treat foreign materials, largely for reexportation as refined copper, in fabricated shapes, and in end products. United States smelters and refineries continue to treat foreign crude materials, both purchased and toll copper.

[2] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

TARIFF

The 2-cent import excise tax, which had gone into effect on July 1, 1950, following a long period of ineffectiveness for one reason or another (*see* Copper chapter of Minerals Yearbook, 1950, p. 485), was suspended again on April 1, 1951, to February 15, 1953, or to termination of the national emergency, whichever came first. The law provided that the Tariff Commission must notify the President within 15 days after the end of any calendar month in which the average price dropped below 24 cents a pound, delivered Connecticut Valley, and within 20 days thereafter the President had to revoke the suspension.

IMPORTS

Imports dropped 29 percent in 1951 and were the smallest since 1947. Refined imports, which declined 25 percent, represented 49 percent of the total, and unrefined copper (blister, converter, etc.) fell 36 percent and made up 29 percent of the total. The usually small scrap class, following an enormous gain in 1950 because unusually large tonnages were received from Japan, had the largest proportionate decrease (86 percent). As usual, Chile was by far the chief source of copper from abroad, supplying 55 percent of the total but 8 percent less than in 1950. Canada, Mexico, and Northern Rhodesia ranked next in importance as sources of United States imports, supplying 9 to 11 percent of the total received. Most, if not all, Rhodesian metal was treated on toll and reexported. All of these countries shipped less copper to the United States in 1951 than in 1950. Peru was the source of 28,502 tons of copper imported in 1950 but only 10,054 in 1951. The Philippines supplied the only increase of consequence—from 10,129 tons in 1950 to 12,608 in 1951.

TABLE 22.—Copper (unmanufactured) imported into the United States, 1942–46 (average) and 1947–51 [1]

[U. S. Department of Commerce]

Year	Short tons of contained copper	Year	Short tons of contained copper
1942–46 (average)	703,155	1949	552,709
1947	413,890	1950	[2] 690,389
1948	507,449	1951	480,376

[1] Data are "general" imports; that is, they include copper imported for immediate consumption plus material entering country under bond.
[2] Revised figure.

EXPORTS

Most of the copper exported from the United States is in advanced forms of manufacture, in which the copper content is not calculable, and in the form of refined copper. Refined-copper exports were 8 percent less than in 1950 and the smallest since 1946. The United Kingdom, as usual, received most of the exports of this class of copper or 53 percent, while the following European countries took most of

WORLD REVIEW

Demand for copper was greater in most important copper-consuming countries of the world in 1951, and mine production rose 5 percent to the highest level since 1943. All large copper-producing nations helped to supply the larger quantities made available in 1951. Mine output in Belgian Congo and Northern Rhodesia increased 9 and 7 percent, respectively, above 1950, and both countries established new peak rates; the United States gained 2, Chile 5, and Canada 2 percent.

Belgian Congo.—The rise in copper production to a new peak in 1951 resulted from the expansion program of the Union Minière du Haut Katanga in progress actively since 1947. The improvements were reported by the chairman to have been chiefly commissioning of facilities at the Bia power station, extension of the copper and cobalt electrolytic plant at Jadotville, and extension of the Kolwezi concentrator.

[1] Copper content of blister produced.
[2] Revised figure.
[3] Smelter output from domestic and foreign ores, exclusive of scrap. Production from domestic ores only, exclusive of scrap, was as follows: 1945, 710,073; 1946, 543,996; 1947, 782,780; 1948, 764,278; 1949, 687,580; 1950, 826,760; 1951, 844,379. Diversion during the war of Belgian Congo matte from its previous destination, Belgium, for resmelting in the United States results in some duplication. The movement ended in 1945.
[4] United States imports.
[5] Figures represent blister copper only. Belgium reports a large output of refined copper, which is not included above as it is believed produced principally from crude copper from Belgian Congo and would therefore duplicate output reported under the latter country.
[6] Data not available; estimate by authors of chapter included in continental and world totals.
[7] Exclusive of material from scrap.
[8] Approximate production.
[9] Includes scrap.
[10] American and British zones only.
[11] Output from U. S. S. R. in Asia included with U. S. S. R. in Europe.

Digitized by Google

The company's earliest mines were in the accessible oxidized deposits, and these are still the most important source of production in the Belgian Congo. Originally supplied by the southern mines, the oxide ore now comes chiefly from the Western group (Kolwezi, Musonoi, and Ruwe), and to a lesser extent from smaller mines to the east (Lukuni, Luiswishi, and Shituru). The ores are concentrated at the mill at Kolwezi and the oxide concentrates sent to the Shituru electrolytic plant [3] at Jadotville. The Jadotville-Panda concentrator suspended operations in mid 1951 owing to exhaustion of oxidized reserves in the Central Group of mines.

Sulfide ore is obtained mainly from the Prince Leopold mine at Kipushi, one of the southeastern group, described in a recent report. It is the source of ore for the Lubumbashi smelter after being concentrated at the Kipushi mill.[4] In two articles published in 1951 describing the mining and treatment of Belgian Congo ores it was stated that the Prince Leopold mine would assure the sulfide supply of the smelter for several years to come. It produces 700,000 tons of ore a year. These articles also gave information regarding cobalt, zinc, and other products of the Union Minière operation.[5]

Canada.—Mine output rose 2 percent in 1951 and was the greatest since 1944; it was, however, 17 percent below the alltime peak of 327,797 short tons in 1940. Refinery output rose 3 percent to 246,312 tons in 1951. Refined-copper consumption was 134,174 tons in 1951, an alltime peak, compared with 106,868 tons in 1950.

TABLE 32.—Copper produced (mine output) in Canada, 1947–51, by Provinces, in short tons [1]

Province	1947	1948	1949	1950	1951 (preliminary)
British Columbia	20,900	21,502	27,055	21,088	**21,906**

[1] Dominion Bureau of Statistics, Department of Trade and Commerce, Government of Canada, Preliminary Report on Mineral Production, 1951.

Ontario produced over half of Canada's total for many years but from 1949 to 1951 only 43 to 48 percent. The copper regularly is derived from the nickel-copper ores of the Sudbury district. The International Nickel Co. of Canada, Ltd., is by far the chief producer of copper in the Province and in Canada, despite the fact that the principal product of the company's mines is nickel. The company delivered 118,477 tons of copper in 1951 compared with 106,474 in 1950 and 110,538 in 1949. The quantities of nickel produced were of the same general order of magnitude but brought much higher prices per unit. Noteworthy progress was made during the year in

the program to develop underground production to offset the approaching exhaustion of open-pit reserves. Mining of the Stobie open pit was completed in August, but production at the Frood open pit was at a rate calculated to preserve the flow from this source until underground mining facilities are ready for planned capacity operations. Underground ore mined was 7,780,143 tons compared with 5,733,269 in 1950 and with a program goal of 13,000,000 tons. Open-pit ore production in 1951 was 4,019,177 tons and in 1950 4,115,755 tons. Proved ore reserves at the end of the year were 253,704,771 tons compared with 252,859,725 tons at the end of 1950. The nickel-copper content was 7,693,122 and 7,669,219 tons, respectively.

Water-borne sand filling from the Copper Cliff concentrator continued to be used in the lower levels of the Frood section of the Frood-Stobie mine for stabilizing older areas as well as for filling current stopes on these levels. Complete change from rock fill to sand fill was expected in 1952. Mill tailings from the Creighton concentrator are similarly employed at lower level stopes of the Creighton mine and are expected to effect the same benefits of more economical mining and higher production from individual working places. A special type of smelting furnace which will use oxygen for flash smelting of copper concentrates instead of smelting with pulverized coal was completed and in experimental operation at the end of the year. The process is expected to permit curtailment of costly coal requirements and greater utilization of sulfur from smelter gases.

The Falconbridge Nickel Mines, Ltd.—the other important producer in Ontario—hoisted 930,164 tons of ore at the Falconbridge mine compared with 881,838 tons in 1950. The McKim mine exceeded its rated production capacity of 500 tons a day, delivering 155,961 tons to the smelter compared with 46,997 tons in 1950. Metallurgical plants at Falconbridge treated 1,083,670 tons, the greatest tonnage on record, of which 679,036 tons was milled and the remainder smelted directly. Ore reserves were increased to 10,102,500 tons of developed ore, averaging 1.64 percent nickel and 0.87 percent copper, and 9,014,000 tons of indicated ore, averaging 1.85 percent nickel and 1.14 percent copper. Inclusion of an ore body found at depth under Fecunis Lake, about 2½ miles east of the Hardy mine, in indicated reserves caused the net increase of 3,235,500 tons in that category.

Quebec is regularly Canada's second most important copper Province. The largest producer here is Noranda Mines, Ltd., operating the Horne mine. A total of 1,328,368 tons of ore was mined in 1951, of which 555,113 tons was direct smelting ore, averaging 2.27 percent copper, 0.186 ounce gold, and 0.42 ounce silver per ton, and 773,255 tons was concentrating ore, averaging 1.90 percent copper, 0.140 ounce gold, and 0.30 ounce silver per ton. The smelter produced 68,943 tons of copper from newly mined material, of which 25,315 tons was from Horne mine ores and concentrates. Developed ore reserves above the 2,975-foot level were 15,626,140 tons of sulfide ore averaging 2.24 percent copper and 0.186 ounce gold per ton. In addition, there was an estimated reserve of 1,500,000 tons averaging 0.7 percent copper in the No. 5 zone of the mine, as well as siliceous fluxing ore and other ore containing little or no copper.

Digitized by Google

East Sullivan Mines had a record year, with an output of 904,762 tons of ore. Ore reserves approximate 4,950,000 tons, of which 4,375,000 is classified as positive, averaging 1.63 percent copper, 1.27 percent zinc, with gold and silver values. A new zinc ore body being developed contains 207,000 tons averaging 8.81 percent zinc and 0.87 percent copper, with gold and silver contents.

The Quemont Mining Corp., Ltd., in which Noranda has a substantial interest and which adjoins the Horne mine, produced 772,781 tons of ore, averaging 1.59 percent copper, and 2.15 percent zinc, with gold and silver values. Metal shipments included 11,468 tons of copper, 12,363 tons of zinc, and gold and silver. The copper concentrate is treated at the Noranda smelter, the zinc concentrate going to the United States. Of the ore produced, about 60 percent was obtained by the cut-and-fill method and 37 percent by sublevel mining; the remainder came from development headings. Ore reserves were virtually unchanged from the beginning of the year at 9,438,000 tons, averaging 1.44 percent copper, 2.65 percent zinc, 0.159 ounce gold, and 0.98 ounce silver per ton.

The Normetal Mining Corp., Ltd., milled 359,266 tons of ore, averaging 2.26 percent copper and 7.41 percent zinc, with gold and silver values; 32,410 tons of concentrates was produced and 130 tons of direct-smelting ore smelted at the Noranda smelter, and zinc concentrates were shipped to the United States. Metals produced were 7,032 tons of copper, 21,354 tons of zinc, 4,637 ounces of gold, and 446,723 ounces of silver. Ore reserves at the end of 1951 were estimated as 2,434,300 tons containing 2.67 percent copper and 8.32 percent zinc, a noteworthy increase over 12 months before.

At the property of the Waite Amulet Mines, Ltd. (controlled by Noranda), 387,754 tons of ore was milled and 12,776 tons of copper, 14,292 tons of zinc, 9,620 ounces of gold, and 346,150 ounces of silver produced. Ore reserves at the Waite mine were increased to 1,037,800 tons owing chiefly to developments at "East Waite," where 1,028,000 tons, averaging 4.1 percent copper, and 3.15 percent zinc, with gold and silver values, was in sight at the year end. Ore reserves at Amulet Dufault dropped to 920,000 tons, of which 695,887 tons averaged 5.7 percent copper and 4.05 percent zinc, 200,000 averaged 2.75 percent copper and 0.6 percent zinc, and 25,000 averaged 1.05 and 5.6 percent, respectively.

The Canadian Copper Refiners, Ltd. (controlled by Noranda), produced 118,000 tons of refined copper compared with 123,200 tons in 1950.

A large additional area of ore was found at the Gaspé Copper property of Noranda Mines, Ltd., in 1951. The ore found in 1951 was 8,025,000 tons, which, combined with the tonnage previously reported, makes a total of 65,000,000 tons. Exploration is expected to develop additional ore. Of the new tonnage, 5,580,000 tons of zone 2 ore averaged 1.45 percent copper, 2,175,000 tons of zone 3 ore averaged 1.76 percent, and 270,000 tons of zone 3 ore averaged 1.45 percent. The 57,000,000 tons had been reported as averaging about 1 percent.

Copper produced in *Saskatchewan* and *Manitoba* regularly has come almost entirely from the Flin Flon mine of the Hudson Bay Mining & Smelting Co., Ltd., and the Sherridon operation of Sherritt Gordon Mines, Ltd. At Hudson Bay's mine 1,823,870 tons of ore

Digitized by Google

was mined, of which 1,820,805 tons, containing 2.40 percent copper and 4.9 percent zinc, with gold and silver values, was milled; in addition, 3,748 tons of direct smelting ore was taken from the stockpile and treated. After allowing for metals due on account of custom concentrates treated on toll, the company shipped blister to the refinery containing 41,878 tons of copper, 146,459 ounces of gold, 1,975,195 ounces of silver, and 128,448 pounds of selenium. Ore reserves at the end of the year, including properties wholly owned or controlled and within trucking distance of Flin Flon, but excluding Cyprus Mines, Ltd., were 18,102,439 tons, averaging 3.15 percent copper and 4.1 percent zinc, with gold and silver values. Cyprus Mines, Ltd., controlled by Hudson Bay, mined 86,514 tons of ore, averaging 3.26 percent copper and 6.9 percent zinc, with gold and silver values. Ore reserves total 129,045 tons.

Following a 1951 output of 248,009 tons of ore containing 5,411 tons of copper, 6,694 tons of zinc concentrate, 2,916 ounces of gold, and 87,495 ounces of silver, reserves at the Sherridon mine were exhausted. From the beginning of operations in 1931 through 1951, 8,531,352 tons of ore were milled and 183,122 tons of copper, 148,961 tons of zinc concentrate, 101,026 ounces of gold, and 3,218,324 ounces of silver produced. At the Bob Lake deposit about 3 miles from the Sherridon, 2,380,000 tons of material, averaging 1.33 percent copper and 1.18 percent zinc, uneconomic at present, has been delimited. Work of moving equipment to Lynn Lake progressed. The small amount of development work carried on during the year confirmed all previous ore indications; the reserves remain at 14,055,000 tons, averaging 1.223 percent nickel and 0.618 percent copper. Sherritt Gordon's program was discussed in the Copper chapter of Minerals Yearbook, 1950. Plans called for construction of a chemical-metallurgical plant at Fort Saskatchewan, 15 miles northeast of Edmonton. An article describing the Lynn Lake operation was published during the year. The new metallurgical process, which will leach the ores with ammonia, is being tested in a pilot plant.[6]

In *Newfoundland* the Falconbridge Nickel Mines, Ltd., entered into an agreement with the Government of the Province, obtaining a 3-year concession comprising about 2,000 square miles. The optional properties of Gull Pond, Rambler, and Tilt Cove, are in the area. Drilling on Gull Pond confirmed the presence of 2,000,000 tons of 1.9-percent copper ore.

Chief producers in *British Columbia* were the Granby Consolidated Mining, Smelting & Power Co., Ltd., and the Britannia Mining & Smelting Co., Ltd. A total of 1,794,882 tons of ore, averaging 0.899 percent copper, was mined at the Copper Mountain property of Granby and treated in the concentrator. Production of salable metals amounted to 12,987 tons of copper, 7,947 ounces of gold, and 172,331 ounces of silver. Ore reserves at the end of the year were 3,100,000 tons plus 600,000 tons of additional possible ore, and excluding all ore that may be reclaimed from caved areas. An extensive new development program was begun in 1951 in the hope of adding a considerable tonnage to that in sight. According to the Yearbook of the American Bureau of Metal Statistics, Britannia produced 7,540 tons of copper

[6] Waldron, Howard L., Sherritt Gordon Develops Lynn Lake Nickel-Copper: Eng. and Min. Jour., vol. 152, No. 11, November 1951, pp. 72-78.

Digitized by Google

in 1951 compared with 7,949 in 1950. Normally concentrates from British Columbia move to the United States for smelting.

Exports of ingots, bars, and billets from Canada in 1951 as compared with 1950 were as follows, by countries of destination, in short tons:

Destination:	1950	1951
United Kingdom	64, 326	51, 918
United States	50, 425	28, 843
France	5, 064	5, 700
Sweden	-------	3, 998
India	6, 683	3, 649
Brazil	858	2, 688
Italy	1, 075	2, 451
Germany	55	1, 258
Switzerland	1, 867	224
Netherlands	1, 872	-------
Other	2, 019	1, 103
	134, 244	101, 832

Exports of copper in ore, matte, regulus, etc., totaled 36,853 (32,299 in 1950) tons, of which the United States was the destination of 28,941 (25,495) tons, Norway 6,310 (6,118) tons, the United Kingdom 1,044 (686) tons, and Germany 558 (no) tons. In addition, 13,291 (15,941) tons of rods, strips, sheet and tubing and 993 (6,233) tons of old and scrap copper were shipped from the country.

Imports of refined copper totaled 1,511 tons in 1951.

Chile.—Mine production of copper rose 5 percent in 1951, or to the highest level since 1948; it was 15 percent less than in 1948 and 24 percent below the peak rate for 1944. Over 20,000 tons of copper was estimated to have been lost in 1951 because of labor strikes, which also affected production adversely in 1950. Strikes at Chuquicamata in May, at all three large mines in June, the Chilean dock strike lasting 2 weeks in September, and the month-long dock strike at New York ports ended November 9 combined to reduce the flow of copper to United States and other markets.

The 1951 annual reports of the Kennecott Copper Corp. and Anaconda Copper Mining Co. to stockholders described the agreement reached between the Governments of Chile and the United States in May with regard to sales of Chilean copper (discussed in the Summary section of this chapter, and efforts of American producers and the Chilean Government to reach agreement with regard to incentive investments. Kennecott's report is quoted as follows:

> In making this agreement it was contemplated that the American companies would increase productive capacity, in return for which, as an incentive for the investment of the necessary amounts of capital, the Chilean Government would revise the existing tax and exchange regulations. Subsequently, the American copper companies and representatives of the Chilean Government reached agreement on the terms of a contract, which contract would be subject to ratification by the Chilean Congress. The contract would grant to the companies the open market exchange rate for their costs of operations, and would provide a straight income tax of 50 per cent and surtax of 17.3 per cent, which surtax would be reduced in direct proportion to increased production of copper over a base established in the contract. While the terms of this contract were agreed upon in November 1951, the contract has not yet been presented to the Chilean Congress for ratification.
>
> The net exchange rate allowed the company for money spent on operations was maintained at 19.32 pesos to the dollar throughout the year; for construction expenditures the rate was held at 60 pesos. At the beginning of 1951, the open market rate was 72.75 pesos, and at the end of the year 92.60 pesos to the dollar.

Outputs of the three leading mines were reported, in metric tons, as follows:

	Ore treated	*Bar copper produced*
Andes	8,042,887	41,586
Braden	8,842,464	155,564
Chuquicamata	15,122,102	163,521

Failure of production to reach World War II levels despite urgent world demand for copper was caused, in addition to strike losses, substantially by the necessity of noteworthy shifts in methods of production to accommodate changes in the nature of ore bodies at Andes and Chuquicamata from oxide to sulfide mineralization. The loss of oxide ores at Andes was not expected to be made up by increased production from sulfide ores. Replacement of lost oxide tonnages at Chuquicamata, on the other hand, appeared to be optional and may be determined in large part by whether or not a favorable atmosphere for increased capital expenditures exists in the country.

The new sulfide plant under construction by the Chile Exploration Co., a subsidiary of the Anaconda Copper Mining Co., since 1949 and described in the Copper Chapter of Minerals Yearbook, 1950, was expected to begin operations in 1952 as planned. The dock strike at New York City delayed shipment of materials and equipment to Chile and moved anticipated full production at the original seven units to the third quarter of 1952. In 1951 it was decided to increase the new concentrator from 7 to 10 units and to enlarge the smelter capacity correspondingly. These changes increased the estimated cost from $90,000,000 to $111,000,000. The full plant was expected to be in operation early in 1953. Output of the new plant and existing oxide plant was expected to exceed 250,000 short tons a year. According to a brochure published by Anaconda in 1952, the Chuquicamata pit produced 4,980,000 short (4,517,756 metric) tons of copper from the start of operations in 1915 to December 31, 1951. To obtain this production, 502,844,000 short (456,170,020 metric) tons of material was mined, of which 350,796,000 (318,235,115 metric) tons was copper oxide ore and 152,048,000 (137,934,905 metric) tons waste material. Remaining in the pit to be mined was 260,000,000 tons, of which 140,000,000 tons was sulfide ore. In addition, a vast body of copper sulfide ore underlay the pit.

At the Braden mine of the Kennecott Copper Corp. further substantial economies were reported as a result of the changeover in progress in 1950. The corporation appropriated $4,794,000 to increase capacity of the mill and began construction. At the smelter, work was in progress on a 40-foot extension of the No. 1 reverberatory furnace to provide for increased production. Efforts to increase available water supply brought favorable results, and increased snowfall also promised an additional supply during winter months.

On December 29 the Government-owned Paipote smelter poured its first blister copper. The plant is near the city of Copiapó, Atacama Province. The Mining Credit Bank (Caja de Crédito Minero) stockpiled raw material for Paipote from midyear, a substantial part of the tonnage being from mines that had previously exported their ores and concentrates. Production of 15,000 tons of blister was expected in 1952; annual capacity is about 18,000 tons.

Chilean exports of the chief types of copper in 1951, by countries, are shown in table 33. Other copper exports from Chile were 3,780 tons of ore (1,418 to Germany, 1,200 to Belgium, 1,000 to Japan, and 162 to the United States); 17,613 tons of concentrates (16,460 to the United States, 1,053 to Germany, and 100 to Sweden); 1,091 tons of scrap (570 to Belgium and 521 to the United States); 1,630 tons of cement copper (800 to Japan, 628 to Belgium, 85 to Argentina, 66 to Germany, and 51 to Italy); and 180 tons of precipitates (all to Germany).

TABLE 33.—Principal types of copper exported from Chile in 1951, by countries, in metric tons

	Refined		Standard (blister)	Total
	Electrolytic	Fire-refined		
United States	96,466	103,308	39,898	**239,672**
Italy	4,693	928	9,640	**15,261**

Denmark		1,524		**1,524**
Switzerland		838		**838**
Other countries	134	1,178	203	**1,515**
Total	118,337	128,371	58,576	**305,284**

Japan.—Production of copper in Japan had trended upward since the lowest of recent years was established in 1946, and this pattern was followed in 1951. Consumption likewise rose. According to the American Bureau of Metal Statistics Yearbook, Japanese consumption of copper was 95,398 metric tons in 1951 compared with 27,240 in 1946. Of the 1951 total, nearly 50 percent was estimated to have come from scrap.

Northern Rhodesia.—Copper production in Northern Rhodesia established a new alltime peak in 1951 for the second successive year. The 1951 output was 7 percent above 1950 and 20 percent over the earlier record in 1940.

The expansion in 1951 resulted despite continuing shortages of coal owing, in large part, to inadequate transportation facilities. According to a recent report, Rhodesia Railways was to receive a £5,000,000 Economic Cooperation Administration loan with provision, among other things, that 21 percent of Southern Rhodesia's output, when production of salable coal and coke equals 200,000 tons a month, was to be made available to Northern Rhodesian copper mines. Moreover, expansion of coal production under way at the Wankie colliery was expected to provide more fuel to Northern Rhodesian copper mines. Part of the additional supplies of coal was expected merely to replace wood burning. The report stated that 125 square miles of forest had been cut to provide fuel equivalent to 780,000 tons of coal. New companies were formed or planned to further exploit Northern Rhodesian mineral deposits, the first of which was the Chibuluma Mines, Ltd., a subsidiary of Mufulira. The ECA granted a loan, the equivalent of about £8,000,000, to this company for developin the

Digitized by Google

mine. The firm will repay the agency in shipments of copper and cobalt to the United States stockpile. Development was proceeding, with annual production of 16,000 tons of copper and 250 tons of cobalt in prospect. Active prospecting was being carried out by a new company, Rhodesian Selection Trust (Services), Ltd., on behalf of four other new companies formed in 1951 (Chisangwa, Mwinilunga, Kadola, and Luapula). Several thousand square miles west of existing copper mines were covered by the exclusive prospecting licenses granted to these companies by the British South Africa Co.[7] Copper companies assigned some of their own labor to the Wankie colliery to alleviate its labor shortage and obtained additional coal as a result. Another report indicated that the Interterritorial Hydroelectric Power Commission had recommended a gigantic hydroelectric power project to provide an eventual capacity of 1,000 megawatts. The project would involve creation of a lake 200 miles long at Karika Gorge on the Zambesi River at a cost of £174,504,000. The commission estimated that at an initial cost of £43,519,000, 385 megawatts could be made available by 1961 for transmission to the copper fields.[8]

A total of 3,970,400 short dry tons of ore, averaging 2.38 percent copper, was mined by Roan Antelope Copper Mines, Ltd., in the fiscal year ended June 30, 1951, or 18 percent above production in 1950. Company concentrates smelted during the year yielded 83,462 short tons of blister copper, compared with 71,184 tons in the year ended June 30, 1950. Blister copper was produced in addition for Nchanga, as reported later. Ore reserves at the end of June 1951 were reported as 90,302,734 short tons of ore averaging 3.27 percent copper.

The Rhokana Corp., Ltd., smelter produced 137,923 short tons of copper in the fiscal year ended June 30, 1951, compared with 134,218 tons in the fiscal year ended June 30, 1950. Of the 1950–51 total, 5,952 tons (17,557 in 1949–50) was blister and 87,193 (72,309) anode copper for Nkana, and 9,648 tons (39,866) was blister and 35,130 (4,486) anode copper for Nchanga. Ore reserves at the end of June 30, 1951, were as follows:

	Short tons	*Copper (percent)*
Nkana north ore body	30, 124, 000	2. 97
Nkana south ore body	20, 165, 000	2. 78
Mindola ore body	52, 316, 800	3. 53
Total	100, 605, 800	3. 21

Rhodesia Copper Refineries, Ltd., produced 68,865 long (77,129 short) tons for Rhokana in 1951 compared with 64,864 long (72,648 short) tons in 1950. The operations of the electrolytic plant were reported hampered by coal shortage, so that the company's expectation that total production would be electrolytic copper in the fiscal year ended June 30, 1951, was not realized. Total electrolytic copper production of Rhodesia Copper Refineries, Ltd., was 107,935 short tons compared with 72.648 tons in the year ending June 30, 1950.

In the year ended March 31, 1951, 1,379,198 short tons of ore averaging 6.47 percent copper was mined by Nchanga Consolidated Copper Mines, Ltd. Developed and partly developed reserves in

[7] Mining Journal (London), Annual Review Number—1952 Edition: Northern Rhodesia, May 1952, p. 119.

Digitized by Google

Nchanga West ore body, as of April 1, were 10,438,731 tons, averaging 7.31 percent copper, a net increase of 1,727,820 tons after allowing for ore mined and adjustments. The total reserves on April 1 were as follows:

	Short tons	Copper (percent) Total	Oxide
Nchanga West	42, 999, 491	6.99	3.03
Nchanga River Lode	2, 280, 000	4.21	2.92
Chingola	2, 000, 000	7.00	6.60
Nchanga	89, 580, 000	3.48	2.19
Total	136, 859, 491	4.65	2.53

Company plans called for expansion of production from 64,000 long (nearly 72,000 short) to 108,000 long (121,000 short) tons, possibly by the end of 1952. In addition to the copper smelted for Nchanga by Rhokana, already reported, the Roan Antelope and Mufulira plants produced from Nchanga concentrates 16,572 and 4,917 short tons of blister, respectively, in the year ended June 30, 1951.

Mufulira Copper Mines, Ltd., mined 3,355,143 short tons of ore, averaging 3.36 percent copper, in the fiscal year ended June 30, 1951. Blister copper production amounted to 86,046 long (96,372 short) tons from company ore, in addition to which Rhokana obtained fluxing ore from Mufulira which yielded 635 long (711 short) tons of blister. Concentrates smelted for Nchanga were additional to the foregoing. Good progress was reported on construction of the new electrolytic refinery. The first section of 36,000 tons was expected to start production in 1952 and doubling of capacity to be effective by 1954. The end product was to be electrolytic cathodes at first but refined shapes when the plant was completed. Estimated ore reserves at the end of the fiscal year follow:

	Short tons	Copper (percent)
Mufulira	114, 132, 000	4.07
Chambishi	25, 000, 000	3.46
Baluba	21, 000, 000	3.47
Chibuluma	7, 300, 000	5.23
Total	167, 432, 000	3.95

Peru.—Mine output of copper rose to 32,274 metric tons in 1951 and to the highest annual total since 1944. The chief copper-producing company is the Cerro de Pasco Corp., which also produces important tonnages of lead, zinc, and silver. The annual report of the company to stockholders reported on conditions in Peru as follows:

Political and economic conditions in Peru were stable throughout the year. The Government's removal of economic controls and elimination of subsidies of various kinds during the past two years were acts of farsighted statesmanship and were well justified.

Due to the increased volume of metal production and higher metal prices, the first year of the operation of the Mining Code, despite reduced tax rates for the mining industry, witnessed a sharp increase in the total amount of taxes payable to the Peruvian Government by the industry. The experience of the past year justifies the expectation that the Mining Code will continue to be advantageous to Peru through stimulating new capital investment in the industry, increased employment and higher production of metals.

The American Smelting & Refining Co. program of diamond drilling on the Toquepala copper project, a porphyry-type deposit in Southern Peru, was almost completed at the end of the year. The company stated that tentative ore-reserve estimates indicated an economic deposit of large size susceptible to mining by open-pit methods. Decision with respect to placing either Toquepala or Quellaveco, 20 miles away and exploration of which was completed in 1950, on an operating basis depended upon detailed investigations of power, water, railway, and port facilities.

By Brooke L. Gunsallus and F. P. Uswald

GENERAL SUMMARY

CRUDE feldspar production in 1951 decreased 2 percent in tonnage but increased 10 percent in value over 1950, according to reports by producers. Imports of crude increased but remained a minor part of the total supply picture. Sales of ground feldspar by merchant mills increased 2 percent in quantity and 9 percent in value. Receipts of crude by merchant mills did not match the increased demand for ground, the difference being met by net withdrawals from stocks. The quantity of ground feldspar sales shipped to the pottery industry increased 17 percent. Sales to the enamel industry decreased 34 percent and to the glass industry 7 percent in 1951 over 1950. In 1951, as in 1950, the output of the pottery industry kept pace with the increase in the demand for its products brought about by postwar expansion in other fields. The production of whiteware, sanitary ware, and high-tension electrical insulators accounted for the greater part of the increase.

Certain restrictions in the use of steel, cobalt, and other materials, imposed in emergency regulations, caused a decided drop in enamel production and resulted in a proportional decrease in the consumption of feldspar. The automotive industry's inability to procure steel automatically lessened the demand for flat glass, a large consumer of feldspar. The substitution of aplite, nepheline syenite, and blast-furnace slag in glass-container formulas also curtailed the demand for feldspar.

Imports of crude feldspar from Canada increased 38 percent in 1951 compared with 1950. Imports of crude nepheline syenite dropped to a negligible quantity in 1951, after having decreased sharply in 1950. Imports of ground nepheline syenite, on the other hand, increased 21 percent in 1951 compared with 1950. These changes were mainly the result of the transfer in 1950 of the grinding operations of the American Nepheline, Ltd., from Rochester, N. Y., to Lakefield, Ontario, Canada. Except for a few scattered shipments, all future imports were expected to be in the ground form. Total sales of aplite in 1951 decreased 5 percent over 1950. Substitution of blast-furnace slag for aplite in glass-container production accounted in part for this decrease.

DOMESTIC PRODUCTION

CRUDE FELDSPAR

Production of crude feldspar in 1951 decreased 2 percent over 1950, but the total value increased 10 percent. The average value per long ton was $7.03 compared with $6.27 in 1950. Eleven states reported production in 1951 the same as in 1950.

GROUND FELDSPAR

Sales of ground feldspar by merchant mills in 1951 reached 454,615 short tons, an increase of 2 percent over 1950, but lower than in 1947 and 1948. The total value increased 9 percent over 1950, and the average selling price per ton was $15.25, an increase of 7 percent. The number of producing States was 14, the same as in 1950.

[1] Excludes potters and others who grind for consumption in their own plants.

As had been the case for several years, North Carolina again was by far the largest grinder of feldspar, followed by Colorado, South Dakota, and Tennessee. Colorado was the only State among the large grinders to show a decrease in 1951; but production in Illinois, New Jersey, New York, and Tennessee also declined. Increases were shown ranging from 1 percent for Connecticut-New Jersey to 33 percent for Georgia-Virginia.

[1] Excludes potters and others who grind for consumption in their own plants.
[2] Included with "Undistributed."
[3] Includes (number of active mills in parentheses) Arizona (1), California (1), Colorado (2 in 1951), Georgia (1 in 1949–50), Illinois (1), New Hampshire (3 in 1949, 2 in 1950), New York (3 in 1949, 1 in 1950), South Dakota (2), and Virginia (2 in 1949–50).

The percentage of total shipments from several States was: North Carolina-Tennessee, 43 percent (45 percent in 1950); Georgia-Virginia, 11 percent; New York-New Hampshire, 7 percent; Connecticut-New Jersey, 6 percent (same in 1950); and Maine, 5 percent (4 percent in 1950).

Digitized by Google

The Appalachian Minerals Co., Monticello, Ga., lost its plant by fire in November 1951 and was not expected to resume operations until the early part of 1953. The feldspar quarries worked by this company were among the few deposits of high potash spar in operation in the United States.

CONSUMPTION AND USES

CRUDE FELDSPAR

Many merchant grinders also mine feldspar, either themselves or through affiliated firms. A large part of their supply of crude feldspar, however, is obtained from small operators who sell their product principally to the merchant mills. The tonnage of feldspar and feldspathic rock treated in flotation plants is increasing.

Most of the consumers of feldspar buy material already ground, sized, and ready for use in their products. Some pottery, enamel, and soap manufacturers, however, purchase all or part of their requirements crude and crush, or grind it to their own specifications in their own mills. Some Canadian crude feldspar is purchased direct by consumers in this country. Manufacturers of artificial teeth annually consume a small tonnage of very carefully selected crude feldspar, which must be free from grit and is marketed at a considerable premium over No. 1 grade commercial feldspar.

GROUND FELDSPAR

The glass, pottery, and enamel industries consumed 99 percent of all ground feldspar in 1951 compared with a like percentage in 1950 and 1949. In 1951, glass accounted for 43 percent, pottery 51 percent, enamel 5 percent, and other industries, including soaps and abrasives, the remaining 1 percent. The tonnage shipped to the pottery industry increased 17 percent, but shipments to the enamel industry decreased 34 percent and to the glass industry 7 percent. Shipments to all other industries using ground feldspar increased about 14 percent in 1951.

TABLE 6.—Ground feldspar sold by merchant mills in the United States, 1949–51, by uses

Use	1949		1950		1951	
	Short tons	Percent of total	Short tons	Percent of total	Short tons	Percent of total

[1] Included with "Other destinations"; separate figure for State not available.
[2] Includes Arkansas, California (1950–51), Colorado, Connecticut, Kentucky, Louisiana, Michigan, Minnesota, Mississippi, Missouri, Oklahoma (1950–51), Puerto Rico (1946–50), Rhode Island, Texas, Washington (1946–50), shipments that cannot be segregated by States, and small shipments to Canada, England, Mexico, and other countries. Also includes specified shipments to Alabama (1949), District of Columbia (1947), Florida (1949), Iowa (1947), Kansas (1948), Maine (1948 and 1950), and North Carolina (1947).

PRICES

Quotations of prices for crude feldspar do not appear in the trade press. Average values are computed from the returns of producers reporting their output annually to the Bureau of Mines. In 1951

Digitized by Google

the average selling price per long ton for all feldspar mined in the United States was $7.03 compared with $6.27 in 1950 and $6.17 in 1949.

The average realization per short ton for ground feldspar in 1951 was $15.25, an increase of over 7 percent from 1950. Of the large producing States, the State having the highest average value per short ton was New Jersey ($26.64), followed by New York ($23.40) and Illinois ($20.47). The lowest average value per short ton was for Colorado ($11.11).

Quotations on ground feldspar appearing in E&MJ Metal and Mineral Market reports for 1951 were the same as in 1949 and 1950 as follows: North Carolina, bulk carlots, 200-mesh, $18.50 per short ton; 325-mesh, $22.50; glass feldspar, No. 18, $12.50; and semigranular, $11.75 (add $3.00 per ton to bulk quotation for bags and bagging). Virginia feldspar presented the same price picture in 1951 as in 1949 and 1950, as follows: No. 1, 230-mesh, $18.50 per ton, and 200-mesh, $17.50; No. 17 glassmakers' feldspar, $11.75, and No. 18, $12.50. Enamelers' feldspar was listed at $15 to $18 throughout 1951.

FOREIGN TRADE [1]

Imports for consumption of crude feldspar in 1951 totaled 17,128 long tons (all from Canada), valued at $146,565. Compared with 1950, there was a 38-percent increase in tonnage and a 74-percent increase in value. This tonnage of crude feldspar imported was the largest since 1948.

TABLE 8.—Feldspar imported for consumption in the United States, 1946–51

[U. S. Department of Commerce]

Year	Crude		Ground		Year	Crude		Ground	
	Long tons	Value	Long tons	Value		Long tons	Value	Long tons	Value
1946	16,365	$127,517	(1)	$2	1949	15,826	$107,925	----	----
1947	16,685	124,587	----	----	1950	12,367	84,136	----	----
1948	31,047	219,785	(1)	328	1951	17,128	146,565	(1)	$26

[1] Less than 0.5 ton.

Ground feldspar exported from the United States, as reported by merchant grinders in 1951, totaled 2,406 short tons, a drop of 41 percent below 1950. Countries of destination were Mexico, Canada, and the United Kingdom.

Cornwall Stone.—Unmanufactured cornwall-stone imports for consumption for 1951 amounted to 944 long tons compared to 1,128 long tons for 1950. Imports of ground cornwall stone were 110 long tons for 1951, about the same as for 1950. The source of imports, either crude or ground, is the United Kingdom.

[1] Figures on imports are compiled by M. B. Price and E. D. Page of the Bureau of Mines, from records of the United States Department of Commerce.

NEPHELINE SYENITE

Nepheline syenite is a quartz-free crystalline rock consisting largely of nephelite and albite and microcline feldspar. Impurities may be iron-bearing minerals, such as black mica and magnetite, and other minerals, such as zircon and corundum. Used originally almost entirely in glass manufacture, substantial quantities now are consumed in making pottery.

Domestic Deposits.—Nepheline syenite occurs in New Jersey, Arkansas, and other localities in the United States, but all the domestic material found thus far in any appreciable tonnage has contained too much iron for ceramic purposes. A thorough study of the Arkansas syenite was initiated in 1950 to determine a method for removing the iron-bearing minerals.[2]

Uses.—Since its first known commercial use about 15 years ago, nepheline syenite has found wide application in the ceramic industry. In the whiteware industry it is used both as a body and as a glaze ingredient for sanitary and electrical porcelain, semivitreous dinnerware, hotel china, fine translucent china, floor- and wall-tile, art pottery, porcelain liners and balls, and kitchenware. The glass industry favors its use because of its high alumina content. In enamels nepheline syenite is used as a frit ingredient in ground and cover coats for sheet steel and cast iron. It is used as a mill addition material for ground-coat enamels. Other industrial applications include its use as a fired bond in abrasive grinding wheels and as an intermediate bond for refractory cements.

Prices.—Quotations on crude nepheline syenite are not reported in trade journals; for years before 1951 the average values per ton of imports for consumption into the United States were taken as an approximation of the crude value for this material. However, the average value of imports for 1951 cannot be taken to be representative of crude values in general because of the small tonnage imported. Only small scattered shipments of crude material were imported in 1951, because the American Nepheline, Ltd., of Ontario, Canada, had closed its grinding plant at Rochester, N. Y., the only syenite grinding plant in the United States. According to the Oil, Paint and Drug Reporter for December 1951, quotations on ground nepheline syenite were as follows: Glass grade (24-mesh), bulk, f.o.b. Rochester, N. Y., $14.25; and pottery grade (200-mesh), bulk, f.o.b. Rochester, N. Y., $18.25. These prices were the same as in December 1950.

Foreign Trade.—Imports of crude nepheline syenite decreased 97 percent from 1950, while imports of ground material increased 21

[2] Manufacturers Record, vol. 120, No. 2, February 1951, p. 76.

Digitized by Google

percent. The average value per ton (foreign market value) of ground nepheline syenite imported was $14.23 in 1951. Canada was the sole supplier of both crude and ground material.

1947	54,382	194,283	-------	-------	1950	8,966	36,453	54,242	703,008
1948	53,570	214,747	7 577	130,860	1951	251	3,595	65,522	932,661

Canada.—The American Nepheline, Ltd., Lakefield, Ontario, Canada, instituted a large expansion of production facilities which would make available an additional 2,000 tons per month of glass and pottery grade material to take care of the steadily increasing demand.[3] The history of this company and the details of the expansion program were given in an article published in 1951.[4]

Europe and Asia.—Deposits of nepheline syenite are known to exist in U. S. S. R. and have been tested for use in the ceramic industry, but production data are not available. Deposits in India and Finland have been reported, but no development work has been recorded.

APLITE

The tonnage of aplite produced in 1951, as well as its value, showed slight decreases under 1950. The only producers of aplite were Dominion Minerals, Inc., Piney River, Va., and Carolina Mineral Co., Inc., Kona, N. C. The operations were in Amherst and Nelson Counties, Va., near Piney River. The Bureau of Mines is not at liberty to publish production or sales data.

New York State College of Ceramics reported substantial progress on aplite research. Aplite appeared to have wider prospective markets in the glass field.

TECHNOLOGY

Although the feldspars vary considerably in chemical composition, their structural form is quite simple, and the properties of the various groups are explained by crystal chemistry concepts.[5]

The practice of froth flotation in the feldspar industry is increasing. A plant to produce 20-mesh glass-grade feldspar with a capacity of 3,500 short tons per month began operations at Spruce Pine, N. C., in August 1951.[6] The demand for high potash feldspar has encouraged the use of flotation in processing feldspar in pegmatite dikes.[7] The origin, classification, and uses of feldspar were discussed in a 1951 article.[8]

WORLD REVIEW

The estimated world production of feldspar in 1951, as shown in table 11, was 725,000 metric tons, an increase of 4 percent compared with 1950. The output of China and U. S. S. R., for which no data are available, was not included in the total.

The production of feldspar in the United States and some other world production districts decreased. Countries showing increases were Argentina, Canada, France, Italy, Japan, and Norway. The ratio of United States output to estimated world output in 1951 was 56 percent compared with 59 percent in 1950. The Department of Natural Resources of Canada announced analysis of samples from Saskatchewan's first major feldspar discovery showed it to be high-quality feldspar suitable for the manufacture of pottery and glass.[9]

TABLE 11.—World production of feldspar, 1947–51, by countries, in metric tons [1]

[Compiled by Helen L. Hunt]

Country [1]	1947	1948	1949	1950	1951
Argentina (shipments)	5,000	(2)	(2)	(2)	(2)

Ferroalloys

By Robert W. Geehan

GENERAL SUMMARY

NEW HIGHS in production and shipments of ferroalloys reached in 1951 reflected increased steel production and particularly the increased demand for and production of alloy steels. Imports of ferroalloys and of the ores needed to produce them increased. Domestic production of these ores also was higher than in 1950. However, demand levels exceeded the supply of many alloying metals; this led to allocations and use restrictions. The value of shipments of ferroalloys in 1951 was $411,294,096.

The ores used to produce ferroalloys are discussed in detail in the following chapters of this volume dealing with particular metals: Chromium, Manganese, Molybdenum, Titanium, Tungsten, Vanadium, and Minor Metals. Cobalt and nickel, which are ordinarily used in alloy steels without the preliminary ferroalloy stage, are also discussed in separate chapters.

PRODUCTION AND SHIPMENTS

Production of ferroalloys reached a new high in 1951 with a total of 2,193,750 short tons. This compares with a previous high of 2,032,980 tons in 1943 and with 1,871,000 tons in 1950 and represents a 17-percent increase over the 1950 production. In 1951 ferroalloys were made in 12 blast-furnace plants, 33 electric-furnace plants, and 2 aluminothermic-furnace plants. Shipments of all classes of ferroalloys from furnaces increased 11 percent in quantity and 22 percent in value over 1950.

Pennsylvania again led all other States in quantity of production (31 percent), shipments (31 percent), and value of shipments (36 percent) of United States ferroalloy transactions. New York followed Pennsylvania in production and value of shipments, but Ohio had the second largest quantity of shipments in 1951. Production and shipments of ferroalloys also were reported from Alabama, California, Florida, Indiana, Idaho, Iowa, Kentucky, Montana, New Jersey, Oregon, South Carolina, Tennessee, Virginia, Washington, and West Virginia.

Ferroalloys containing manganese are used to remove oxygen and sulfur from steel, but their most important function is to provide manganese in amounts sufficient to combine with any sulfur that remains in the steel. Steel containing sulfur becomes brittle when hot; if the sulfur is combined with manganese it forms relatively harmless segregations and the difficulties in hot-working are minimized. As sulfur is present in the raw materials from which nearly all steel is produced, nearly all steel requires manganese. Another important use is in the production of manganese-type alloy steels and castings.

Calcium molybdate and compounds						
Other ferroalloys [1]	281,131	289,863		364,557	369,919	
Total	1,871,000	1,982,216	337,131,284	2,193,753	2,207,350	411,294,096

[1] Silicomanganese, manganese briquets, ferrochromium, ferrocolumbium, ferroboron, zirconium-ferrosilicon, and miscellaneous ferroalloys.

Ferroalloys containing silicon have uses similar to those containing manganese; both may be considered scavengers, in that they either remove objectionable impurities or render them relatively harmless, and both are used to produce alloys. Silicon compounds are used mainly to remove oxygen from steel, and the consumption follows the trend for total steel production. Both silicon and manganese are frequently added to the same heat of steel; silico-manganese is often used when the combined action is desired. Silicon metal is not a ferroalloy but is included in this chapter because it has similar uses.

Ferromanganese.—The ferromanganese produced in 1951 averaged 76.05 percent manganese, a decrease of 0.91 percent from 1950, and came from 8 electric-furnace and 8 blast-furnace plants; this was an increase of 2 electric-furnace plants over 1950. Of the manganese ore used in 1951 for manufacturing ferromanganese, 93 percent was foreign, the same percentage as in 1950. The steel industry consumed nearly all of the ferromanganese used in 1951.

Canada replaced Norway as the source of the largest amount of imported ferromanganese in 1951, while Norway and France continued to be important sources, and very small quantities were received from Germany, Japan, and Yugoslavia. Expansions of plant facilities were described.[1]

Producer	Plant	Alloy
American Agricultural Chemical Co.	South Amboy, N. J.	Ferrophosphorus (byproduct).
Anaconda Copper Mining Co	Anaconda, Mont. Black Eagle, Mont.	Ferromanganese.
Bethlehem Steel Co	Johnstown, Pa.	Do.
Climax Molybdenum Co	Langeloth, Pa.	Ferromolybdenum, calcium molybdate, molybdenum oxide, molybdenum silicide, ammonium molybdate, oxide briquets, molybdenum trioxide, sodium molybdate, cobalt molybdenum, molybdenum sulfide.
Electro Metallurgical Co	Alloy, W. Va. Ashtabula, Ohio Columbiana, Ohio Holcomb Rock, Va. Niagara Falls, N. Y. Portland, Oreg. Sheffield, Ala.	Ferromanganese, silicomanganese, manganese briquets, ferrosilicon, silicon briquets, zirconium-ferrosilicon, ferrochromium, chromium briquets, ferrotungsten, ferrovanadium, ferroboron, ferrocolumbium, ferrotitanium.
General Abrasive Co., Inc.	Niagara Falls, N. Y.	Ferrosilicon (byproduct).
Globe Iron Co	Jackson, Ohio	Silvery pig iron.
Hanna Furnace Corp	Buffalo, N. Y.	Do.
Inland Steel Co	E. Chicago, Ind.	Spiegeleisen.
Jackson Iron & Steel Co	Jackson, Ohio	Silvery pig iron.
Kaiser Aluminum & Chemical Corp.	Permanente, Calif.	Ferrosilicon.
Keokuk Electro-Metals Co	Keokuk, Iowa Wenatchee, Wash.	Ferrosilicon, silvery pig iron.
E. J. Lavino & Co	Reusens, Va. Sheridan, Pa.	Ferromanganese.
Metal & Thermit Corp	Carteret, N. J.	Ferrotitanium.
Molybdenum Corp. of America	Washington, Pa.	Ferrotungsten, ferromolybdenum, molybdic oxide, ferroboron, manganese boride, calcium molybdate.
Monsanto Chemical Co	Anniston, Ala. Columbia, Tenn.	Ferrosilicon (byproduct), ferrophosphorus (byproduct).
New Jersey Zinc Co	Palmerton, Pa.	Spiegeleisen, ferromanganese.
Ohio Ferro-Alloys Co	Philo, Ohio Tacoma, Wash.	Ferrosilicon, simanal, ferrochromium, ferrosilicon boron.
Oldbury Electro-Chemical Co	Niagara Falls, N. Y.	Ferrophosphorus (byproduct).
Pacific Northwest Alloys, Inc.	Mead, Wash.	Ferrosilicon, ferrochromium, ferrochrome silicon.
Pittsburgh Metallurgical Co	Calvert City, Ky. Charleston, S. C. Niagara Falls, N. Y.	Ferrosilicon, silvery pig iron, ferrochromium, ferrochrome silicon.
Tennessee Products & Chemical Corp. (Southern Ferro-Alloys Div.).	Chattanooga, Tenn.	Ferromanganese, manganese briquets, ferrosilicon, silicon briquets.
Tennessee Valley Authority	Muscle Shoals, Ala.	Ferrophosphorus (byproduct).
Titanium Alloy Mfg. Div., National Lead Co.	Niagara Falls, N. Y.	Ferrotitanium, ferrocarbontitanium.
U. S. Steel Corp. subsidiaries	Clairton, Pa. Etna, Pa. Duquesne, Pa. Ensley, Ala.	Ferromanganese, speigeleisen.
Vanadium Corp. of America	Niagara Falls, N. Y. Bridgeville, Pa.	Ferrosilicon, silicon briquets, alsifer, ferrochromium, ferrochromium briquets, ferrovanadium, ferrotitanium, grainals, ammonium meta vanadate, titanium aluminum, ferrocarbontitanium, cupro vanadium, manganese vanadium, alumino vanadium.
Victor Chemical Works	Mt. Pleasant, Tenn.	Ferrophosphorus (byproduct).
Virginia-Carolina Chemical Corp.	Nichols, Fla. Charleston, S. C.	Do.
Westvaco Chemical Div., Food Machinery & Chemical Corp.	Pocatello, Idaho	Do.

Spiegeleisen.—Production of this alloy increased 82 percent in 1951 as compared to 1950; this is the first increase in the production of this alloy since 1947. Spiegeleisen is in effect a high (15 to 30 percent) manganese pig iron containing 4.5 to 6.5 percent carbon; it is made from the lower grade manganese-bearing material.

Silicomanganese.—The silicomanganese produced in 1951 averaged 67 percent manganese. This alloy is used to introduce manganese into low-carbon killed steels because of its low carbon-manganese ratio.

Digitized by Google

Manganese Briquets.—Manganese briquets are made from ferromanganese or silicomanganese that has been crushed and bonded into briquets containing 2 pounds of manganese.

Ferrosilicon.—From the standpoint of tonnage, more ferrosilicon is produced than any other ferroalloy. Ferrosilicon production and shipments, listed in table 1, includes silvery pig iron, ferrosilicon of various grades, and ferrosilicon briquets. The average percent of silicon content of these products in 1951 was 9.3, 40, and 40, respectively. Silvery pig iron is produced in blast furnaces, ferrosilicon is manufactured in electric furnaces, and ferrosilicon briquets are produced from the latter and are standardized as to silicon content.

TABLE 3.—Consumption of ferrosilicon, silicon metal, and miscellaneous silicon alloys in the United States in 1951, by end use, in short tons

Alloy	Percent silicon content	Steel ingots and castings [1]	Steel castings [1]	Iron foundry and miscellaneous	Total
Silvery pig iron	5–13	12,742	21,357	197,529	231,628
Do.	14–20	60,618	9,931	126,827	197,376
Ferrosilicon	[2] 21–55	168,135	21,996	23,229	213,360
Do.	56–70	19,576	371	559	20,506
Do.	71–80	45,174	1,289	11,757	58,220
Do.	81–89	4,610	81	1,966	6,657
Do.	90–95	6,005	121	1,990	8,116
Silicon metal or refined silicon		8	5	11,936	11,949
Other silicon alloys [3]		24,641	5,357	48,675	78,673
Total		341,509	60,508	424,468	826,485

[1] Data for castings made by companies that also produce steel ingots are included with "Steel ingots and castings" and excluded from "Steel castings."
[2] Nearly all this material is in the range from 40 to 55 percent silicon.
[3] Including Sil-X, alsifer, and ferrosilicon briquets.

Table 3 lists the various grades of ferrosilicon and the silicon metal consumed, along with a breakdown of the end use based on a tabulation that lists the entire consumption of each reporting plant under the most important use at that location. Silvery pig iron is used chiefly by iron foundries. Standard-grade ferrosilicon (about 50 percent silicon), consumed mainly by the steel industry, is used as a deoxidizer and solidifier in manufacturing most grades of killed and semikilled steel. The higher grade alloys are used in ladle additions in gray-iron foundries, in the manufacture of high-silicon steel for use in electrical equipment and spring steel, and in plants producing magnesium by the ferrosilicon method. Ferrosilicon briquets are used at both steel plants and iron foundries. Silicon alloys containing other elements are produced for special uses.

Silicon Metal.—Nearly three-quarters of the silicon metal consumed is used by the aluminum industry. Much of the remainder is used at plants producing "silicone" products and at establishments manufacturing low-carbon alloys.

Ferrophosphorus.—All ferrophosphorus in 1951 was produced in electric furnaces as a byproduct in the manufacture of phosphate fertilizers and other chemicals. Ferrophosphorus is used primarily as an addition agent in manufacturing certain open-hearth sheet steels to prevent sticking of sheets on packrolling. Exports were at a new high level of 55,044 tons; the previous high was 52,988 tons in 1948.

Digitized by Google

Ferrotungsten.—The ferrotungsten produced in the United States during 1951 was made in electric furnaces from both foreign and domestic ores. The total consumption of tungsten concentrates in the United States during the year was 11,989 short tons (60 percent WO_3 basis), 2,310 tons of which was consumed in manufacturing ferrotungsten. This product is mainly used as a source of tungsten in high-speed steels. However, the present practice in the industry is to charge high-purity scheelite concentrates to supply much of the needed tungsten and to use ferrotungsten to bring the tungsten up to exact specifications.

Ferrochromium.—All ferrochromium produced in the United States in 1951 was made in electric furnaces, chiefly from foreign ores. Ferrochromes are divided into two main classes—high-carbon, containing 65 to 70 percent chromium with carbon contents ranging from 4.5 percent to 8.5 percent in the various grades; and low-carbon, containing 67 to 72 percent chromium with carbon ranging from a maximum of 0.03 percent to 2.00 percent. Special ferrochromes, such as nitrogen-bearing and silicon-manganese ferrochromes are manufactured for special uses. The low-carbon grades of ferrochromium are used in the stainless steels and high-temperature alloys, which contain relatively high percentages of chromium and low percentages of carbon, and the high-carbon grades in other types of chromium-bearing steels. Reported consumption of ferrochromium in the United States in 1951 was 195,307 short tons compared with 147,911 tons in 1950 and 87,764 tons in 1949. This consumption was reported by consumers that normally use about 85 percent of the total. Imports increased 18 percent over those of 1950, but exports declined 31 percent in the same period.

Ferrochrome Silicon.—During 1951 there was an increased use of ferrochrome silicon. This product, also referred to as chrome silicide, is sold at lower prices, in terms of chromium content, than low-carbon ferrochromium. A similar alloy, containing aluminum in addition to the chromium and silicon, is also produced; still another variation contains sodium nitrate.

Ferromolybdenum.—The ferromolybdenum produced in 1951 was made by the aluminothermic and electric furnace processes and used domestic concentrates. The alloy was produced in only two plants during the year. The average molybdenum content of the material produced in 1951 was 61 percent.

Molybdic Oxide, Calcium Molybdate, and Other Molybdenum Compounds.—Molybdenum compounds used as alloying agents in the production of iron and steel are included with ferroalloys. These materials are used more extensively than ferromolybdenum because of their lower cost.

Ferrotitanium.—Most of the ferrotitanium in 1951 was produced in electric furnaces, but a small quantity was made by the aluminothermic process. The ferrotitanium produced in 1951 contained a higher percentage of titanium than in the preceding year, the average of all grades in 1951 being 24.5 percent Ti compared with 24.0 percent in 1950. Both foreign and domestic ores of titanium (ilmenite and rutile) were consumed in its manufacture. A number of grades of ferrotitanium are available for use in steel making. The low-carbon grades are used chiefly in manufacturing stabilized austenitic stainless

Digitized by Google

steels to render them resistant to intergranular corrosion in service. The high-carbon grades are used as deoxidizers and scavengers. In medium- and high-carbon killed steels the higher-carbon varieties of ferrotitanium are used as the final deoxidizer to prevent segregation and the occurrence of objectionable inclusions, and in some cases to control grain size.

Ferrovanadium.—Nearly all the ferrovanadium produced in 1951 was made in electric furnaces, but a small amount was produced by the aluminothermic method. Both foreign and domestic ores were used. This alloy averaged 53.5 percent vanadium in 1951, compared with 53 percent in 1950 and 50 percent in 1949. Up to 0.10 to 0.25 percent of vanadium is added to engineering steels—usually to the ladle in open-hearth practice and to the furnace in basic electric practice. In high-speed steels the percentage ranges from approximately 1.00 to 2.50 percent, and some steels are made with a higher vanadium content. Vanadium is also employed to prevent age hardening in low-carbon rimmed steels.

Ferrocolumbium.—Columbium is used chiefly in manufacturing stabilized austenitic stainless (Cr–Ni) steels. It is also employed to reduce the air hardening characteristic of straight chromium steels of the corrosion-resistant type. In both 1950 and 1951 the output of ferrocolumbium averaged 56 percent columbium compared with 57 percent in 1949 and was produced in electric furnaces.

Zirconium-Ferrosilicon.—The zirconium-ferrosilicon produced in 1951 averaged 14 percent Zr, as in the previous year. Zirconium, a deoxidizer and scavenger, combines readily with oxygen, nitrogen, and sulfur, eliminating them from the steel bath or minimizing their effect. Formation of zirconium nitride reduces age hardening in deep-drawing steels; and the formation of zirconium sulfide, as with manganese sulfide, diminishes hot shortness. The addition of over 0.10 percent zirconium to steels usually results in grain refinement. The alloy is used in place of ordinary ferrosilicon but is more effective for the purposes stated.

Ferroboron.—The scarcity of many of the elements used in ferroalloys was an added factor in the development of boron steels during 1951, and the production of ferroboron in 1951 was eight times that of 1950. Boron is used in steel to increase the hardenability—the depth to which the steel will harden when quenched. The amount of boron added is ordinarily only a few thousandths of 1 percent, and it is most effective in the lower carbon steels. Boron can replace part of the other alloying elements, such as manganese, chromium, molybdenum, and nickel, if they are intended only to aid hardenability, but does not provide effects such as retarding softening or resisting creep at elevated temperatures. The uses of boron steel were described in several technical articles.[2]

FOREIGN TRADE [3]

Canada, Norway, and France continued to be the important sources of ferromanganese. The original sources of the manganese ore used to produce the imported ferromanganese were largely French Morocco and the Gold Coast. Canada and Norway supplied most of the imports of ferrosilicon, Japan was the source of most of the imported ferrotungsten, and Canada and Sweden were the important sources of ferrochromium.

TABLE 4.—Ferroalloys and ferroalloy metals imported for consumption in the United States, 1950–51, by varieties

[U. S. Department of Commerce]

Variety of alloy	1950			1951		
	Gross weight (short tons)	Content (short tons)	Value	Gross weight (short tons)	Content (short tons)	Value

Fluorspar and Cryolite

By Hubert W. Davis

GENERAL SUMMARY

RECORD consumption and imports of fluorspar, higher prices, reduction in rate of duty on acid-grade fluorspar, an increase in the rate for lower grade, and a shortage of acid-grade were outstanding features of the fluorspar industry in 1951.

Although shipments of fluorspar from mines in the United States established a postwar high and were 15 percent greater than in 1950, they fell far short of meeting industry's requirements. The deficit was met by imports, which established a new record and were 10 percent greater than in the former record year 1950. Record consumption of fluorspar at basic open-hearth steel and hydrofluoric-acid plants and a slight gain in consumers' stocks were chiefly responsible for the accelerated activity in fluorspar in 1951.

Illinois, which established a new record, maintained its rank as the premier producer of fluorspar in 1951 by supplying 59 percent of the total domestic shipments. Moreover, shipments from Illinois were 32 percent greater than in 1950 and 3 percent over 1943, the previous record year. Arizona, Colorado, Idaho, New Mexico, and Tennessee also shipped more fluorspar than in 1950, but Kentucky, Montana, Nevada, and Utah shipped less. Shipments from Idaho were reported for the first time, and the shipments from Tennessee were the first since 1943.

For the eleventh consecutive year, Mexico was the largest supplier of foreign fluorspar to the United States; however, it supplied proportionately less in 1951 than in recent years. Despite the fact that imports from Mexico were 12 percent less than in 1950, they were the third highest on record. Less fluorspar was also received from France and Spain. These losses, however, were more than offset by larger imports from Algeria, Canada, Germany, Italy, and Union of South Africa.

The steel industry, which set a new production record in 1951, continued to be the predominant user of fluorspar; and, despite the fact that its total consumption of fluorspar established a new record, it absorbed proportionately less (55.7 percent) of the total consumed in 1951 than in 1950 (56.5 percent). Use by the industry exceeded that in 1950 by 15 percent; and, because of the higher steel output in 1951 and the larger utilization of fluorspar per ton of steel made than in 1950, its total consumption exceeded the record made in 1942 by 14 percent. The average consumption of fluorspar per long ton of basic open-hearth steel produced was 5.8 pounds in 1951 com-

Digitized by Google

pared with 5.5 pounds in 1950 and 6.4 pounds in 1942. The hydrofluoric-acid industry—the second largest utilizer of fluorspar—consumed 22 percent more than in 1950 and 17 percent more than in the former record year 1944, or 31 percent of the total in 1951 compared with 29 percent in 1950. Consumption of fluorspar by the glass industry was greater, but less was used by the enamel trade.

Deliveries of fluorspar to steel plants in the United States increased to 287,031 short tons (271,869 tons in 1950), and those to glass and enamel plants rose to 43,624 (41,534 tons in 1950).

The average composite selling price ($40.15 a short ton) of all grades of fluorspar (both domestic and foreign) delivered to consumers in the United States in 1951 was $6.60 more than in 1950.

The total quantity of fluorspar shipped from mines and imported into the United States from about 1870 through 1951 was approximately 10,136,000 short tons—about 81 percent from domestic mines and 19 percent from foreign sources.

TABLE 1.—Salient statistics of fluorspar in the United States, 1942–51, in short tons

Year	Shipments from domestic mines	Foreign trade		Consumption	Industry stocks at end of year		
		Imports for consumption	Exports		Domestic mines [1]	Consumers' plants	Total
1942	360,316	2,151	9,020	360,800	19,429	96,000	115,429
1943	406,016	43,769	9,068	388,885	19,026	105,933	124,959
1944	413,781	87,200	1,980	410,170	19,021	98,446	117,467
1945	323,961	104,925	1,420	356,090	19,863	103,148	123,011
1946	277,940	29,852	1,729	303,190	18,957	98,663	117,620
1947	329,484	78,725	1,180	376,138	33,101	114,150	147,251
1948	331,749	111,626	666	406,269	37,344	146,869	184,213
1949	236,704	95,619	802	345,221	37,039	130,621	[2] 167,660
1950	301,510	164,634	740	426,121	19,038	164,685	[2] 183,723
1951	347,024	181,275	1,173	497,012	13,283	169,126	[2] 182,409

[1] Finished fluorspar only.
[2] In addition, importers held 11,000 tons in 1949, 7,500 tons in 1950, and 2,845 tons in 1951 (none in 1942–48).

PRODUCTION

Production of finished fluorspar totaled 341,300 short tons, including 183,624 tons of flotation concentrates; however, this output also included 2,300 tons of finished fluorspar recovered from milling crude ore that had been mined before 1951. Thus, total new production (expressed in terms of finished fluorspar) was 339,000 tons in 1951, compared with 274,100 tons in 1950. Of the mine output in 1951, 8 mines (producing over 10,000 tons each) supplied 142,300 tons or 42 percent; 11 mines (producing 5,000 to 10,000 tons each) supplied 86,700 tons or 26 percent; 29 mines (producing 1,000 to 5,000 tons each) supplied 74,900 tons or 22 percent; and 10 mines (producing 500 to 1,000 tons each) supplied 7,100 tons or 2 percent. Thus 58 mines produced 311,000 tons or 92 percent of the total. Of the remaining output (28,000 tons or 8 percent), some (in quantities ranging from a few tons to 500 tons) came from an undetermined

Digitized by Google

number of small mines and prospects, but much was derived from treated tailings from previous milling operations.

In 1951 mines operated by consumers produced 85,200 tons of finished fluorspar compared with 73,700 tons in 1950.

Fluorspar shipments from domestic mines in 1951 aggregated 347,024 short tons valued at $14,369,521, increases of 15 percent in quantity and 35 percent in value over 1950. Of the 1951 total, 63,290 tons was shipped by river or river-rail for delivery to consumers compared with 68,933 tons in 1950.

Illinois (59 percent) and Kentucky (20 percent) supplied 79 percent of the fluorspar shipped in 1951 compared with 78 percent in 1950. Shipments from Illinois and Kentucky were 16 percent more than in 1950 compared with a gain of 11 percent from other producing States.

The average value of all grades of domestic finished fluorspar shipped in 1951 ($41.41) established a new peak and was $6.19 more than the previous high in 1950.

Fluorspar shipments in 1951 comprised 160,666 tons of fluxing gravel (including 19,660 tons of flotation concentrates, which were blended with fluxing gravel) and foundry lump and 186,358 tons of ground and flotation concentrates. The bulk of the fluxing-gravel and foundry-lump fluorspar was shipped to steel plants and iron foundries, but a comparatively small tonnage moved to plants making cement, ferro-alloys, nickel, basic refractories, and fluxing compounds and to smelters of secondary metals. Of the ground and flotation concentrates shipped in 1951, hydrofluoric-acid plants took 66 percent (includes quantities going to the National Stockpile), and glass and enamel plants 21 percent; the remainder went chiefly to aluminum- and magnesium-reduction works; to manufacturers of steel, ferro-alloys, and welding rods; and to smelters of secondary metals.

Cement	81		Grand total	301,510	347,024
Miscellaneous	2,131	4,619			

[1] Fluxing gravel includes (and flotation concentrates exclude) the following quantities of flotation concentrates blended with fluxing gravel: 1950, 11,240 tons; 1951, 19,660 tons.
[2] Includes pelletized gravel.
[3] Includes shipments to National Stockpile.

Shipments, by Uses.—As is evident from table 5 and figure 1, the predominant purchaser of fluorspar is the steel industry, which also consumes substantial quantities of hydrofluoric acid and sodium fluoride, for which fluorspar is the basic material.

[1] Includes shipments to National Stockpile.

Stocks at Mines.—According to the reports of producers, the quantity of fluorspar in stock at mines or shipping points at the close of 1951 totaled 75,116 tons, or virtually the same as in 1950. These stocks comprised 13,283 tons of finished fluorspar and 61,833 tons of crude fluorspar (calculated to be equivalent to 25,000 tons of finished fluorspar).

[1] This crude (run-of-mine) fluorspar must be beneficiated before it can be marketed.

CONSUMPTION

Tables 7 and 8 give data on consumption and consumers' stocks of fluorspar.

TABLE 7.—Fluorspar (domestic and foreign) consumed and in stock in the United States, 1950–51, by industries, in short tons

Industry	1950			1951		
	Consumption	Stocks at consumers' plants Dec. 31	In transit to consumers' plants Dec. 31	Consumption	Stocks at consumers' plants Dec. 31	In transit to consumers' plants Dec. 31
Basic open-hearth steel	212,928			242,180		
Electric-furnace steel	27,567	131,924	4,307	34,058	138,113	5,062
Bessemer steel	307			416

[1] Fluorspar used in making artificial cryolite and aluminum fluoride (aluminum raw materials) is included in the figures for hydrofluoric acid, an intermediate in their manufacture.
[2] Figures on consumption represent fluorspar used as a flux; *see* footnote 1.

TABLE 8.—Production of basic open-hearth steel and consumption and stocks of fluorspar (domestic and foreign) at basic open-hearth steel plants, 1947–51

	1947	1948	1949	1950	1951
Production of basic open-hearth steel ingots and castings.....long tons	68,506,000	70,830,000	62,634,000	76,873,000	83,118,000
Consumption of fluorspar in basic open-hearth steel production.....short tons	189,773	207,342	183,045	212,928	242,180
Consumption of fluorspar per long ton of basic open-hearth steel made.....pounds	5.5	5.9	5.8	5.5	5.8
Stocks of fluorspar at basic open-hearth steel plants at end of year.....short tons	68,400	106,300	97,400	128,300	133,100

Digitized by Google

Fluorspar was reported consumed in 42 States and the District of Columbia in 1951, but 3 States—Illinois, Ohio, and Pennsylvania—used 246,664 tons or 50 percent of the total consumption. Pennsylvania was again the chief consuming State; it ranked first in consumption of fluorspar in both steel and glass. Illinois maintained its rank in 1951 as the largest consumer of fluorspar in hydrofluoric acid.

Table 9 shows, so far as possible without revealing the figures of individual companies, the consumption of fluorspar by States in 1950 and 1951.

TABLE 9.—Fluorspar (domestic and foreign) consumed in the United States, 1950–51, by States, in short tons

State	1950	1951	State	1950	1951
Alabama, Georgia	12,882	14,068	Kentucky	15,238	20,760
Arkansas, Florida, Louisiana, Mississippi, North Carolina, South Carolina	26,017	32,637	Maine, Massachusetts, Rhode Island, New Hampshire	1,530	2,078
California	10,725	12,886	Maryland	7,437	8,240

			West Virginia	3,937	5,766
			Total	426,121	497,012

REVIEW BY STATES

Arizona.—Fluorspar production in Arizona in 1951 established a new record—1,623 short tons compared with 952 tons in 1950 and with 1,608 tons in the previous record year 1939. The 1951 output came chiefly from the Lone Star mine in Cochise County, and most of it was shipped to the flotation mill at Los Lunas, N. Mex. Some of the output, however, was shipped to the Illinois-Kentucky district for blending with other fluorspar, and some was shipped direct to steel plants. Small outputs were made by the Jumbo, Lucky Strike, and West End Spar mines in Maricopa County and shipped to steel and cement plants; and the small output in Greenlee County was shipped to the flotation mill at Los Lunas, N. Mex.

Colorado.—The output of 20,600 short tons of finished fluorspar in Colorado in 1951 compared with 18,500 tons in 1950 reversed a downward trend that had persisted for six consecutive years. In addition, crude ore equivalent to 1,300 tons of finished fluorspar was mined but not milled in 1951. Thus, new production (expressed in terms of finished fluorspar) totaled 21,900 tons compared with 17,952 tons in 1950. Output came from Boulder, Chaffee, Douglas, Jackson, and Park Counties.

Digitized by Google

Shipments of fluorspar from Colorado likewise increased after declining for six consecutive years and were 20,661 tons compared with 18,489 tons in 1950.

The Ozark-Mahoning Co., operating a flotation mill near Jamestown, produced 3.5 percent more flotation concentrates in 1951 than in 1950. The flotation-mill feed comprised ore from the Afterthought, Argo, Blue Jay, Emmett, and Spartan No. 5 mines in Boulder County, Northgate mine in Jackson County, and White Eagle mine in Luna County, N. Mex. The concentrate recovered from White Eagle ore, as well as that shipped, has been credited in the statistics to New Mexico. The company acquired the Northgate mine in October 1951. Under an agreement between Defense Materials Procurement Agency and Ozark-Mahoning Co. a flotation plant to produce about 25,000 tons of acid-grade concentrates annually was under construction at Northgate, Colo., the latter part of 1951. Ore will come from company mines adjoining the mill, which was expected to be completed mid-1952.

The flotation mill of the General Chemical Division, Allied Chemical & Dye Corp., near Jamestown produced 57 percent more concentrates than in 1950. The flotation-mill feed came from the company-owned Burlington mine in Boulder County.

Reynolds Mining Corp. acquired the Poncha mine and the flotation mill serving it near Chaffee County, Salida, Colo.; production of concentrates was begun in November. Development of the mine and improvements in the mill were begun.

Small outputs of fluorspar were made from the Bear Cat prospect in Park County and from a prospect in Douglas County.

Idaho.—The first commercial production of fluorspar in Idaho was made in 1951 by Fluorspar Mines, Inc., which had acquired the Chamac fluorspar deposits and a flotation mill near Myers Cove, Lemhi County. The flotation mill was rehabilitated and production of acid-grade concentrates begun August 1. Development was being done in conjunction with mining operations. Expansion of mill facilities was contemplated. The flotation mill was completed in 1944 by Chamac Mining Co., but no commercial concentrates were produced by that company.

Illinois.—Illinois continued to lead the fluorspar-producing States in 1951 with an output of finished fluorspar totaling 205,300 short tons compared with 150,500 tons in 1950. New production (expressed in terms of finished fluorspar) also was 205,300 tons in 1951 compared with 146,700 tons in 1950. About 92 percent of the 1951 production came from Hardin County and the remainder from Pope County. Some Kentucky fluorspar is milled in Illinois, and some Illinois fluorspar is milled in Kentucky; the finished fluorspar so recovered, as well as that shipped, is credited in the statistics to the State of origin. The Argo, Blue Diggings, Crystal, Deardorff, Douglas, East Green, Empire, Fairview, Geely Shaft, Hawkins, Interstate, Jefferson, Mahoning Shafts Nos. 2, 3, 4, and 5, Minerva, North Boundary, Pell Shaft, Redd, Rosiclare, Recovery Shaft, North Green, and Victory properties supplied about 95 percent of the fluorspar produced in Illinois in 1951. Some of the remainder came from many mines and prospects, chiefly the Austin, Baker, Blue Valley, Grandpier, Hamp, Pell, Hillside, Jackson, Knox, Lead Hill, Humm, Mahoning Shaft

Digitized by Google

No. 16, Rose Creek, Dimick, Tems, Twitchell, Eureka-Deatherage, Wall, and Tri-State; some was recovered from tailings from previous milling operations, chiefly the Hillside mine tailings.

Shipments of flourspar from Illinois (204,328 tons) established a new record in 1951; they exceeded those in 1950 by 32 percent and contributed 59 percent of the total domestic shipped. Of the 1951 total, 45,056 tons was shipped by river or river-rail to consumers compared with 31,699 tons in 1950.

The Alcoa Mining Co. produced 22 percent more flotation concentrates in 1951 than in 1950. The mill feed comprised ore from the company-operated Argo, Blue Diggings, Hamp, and Fairview mines. The Argo-Blue Diggings vein system was worked through the Fairview shaft. Work was begun during 1951 to develop the Good Hope vein by means of crosscuts from the Fairview shaft. The Good Hope vein has not been mined for more than 30 years. Output of acid-grade concentrates in 1951 was the third-largest in the company history, being exceeded only by that in 1943 and 1944.

Production of finished fluorspar by Crystal Fluorspar Co., Inc., was 72 percent larger in 1951 than in 1950. The Crystal mine was flooded 6½ months in 1950. The company also operated the Jefferson mine, which produced 2.5 times more fluorspar than in 1950.

Output of fluorspar flotation concentrates at the Rosiclare plant of Ozark-Mahoning Co. established a new record in 1951; it was 14 percent more than in 1950 and 7 percent more than the previous high of 1948. The mill feed comprised ore from the Deardorff, East Green, Mahoning Shafts Nos. 2, 3, 4, 5, and 16, and North Green mines near Cave in Rock, Ill., the Rose Creek mine near Herod, Ill., the Delhi-Babb mine near Salem, Ky., the Commodore mine near Marion, Ky., the Northgate mine near Northgate, Colo., the White Eagle mine near Deming, N. Mex., and some purchased ore, chiefly from the Alcoa Mining Co., Crystal Fluorspar Co., Inc., and Rosiclare Lead & Fluorspar Mining Co. The concentrates recovered from milling ore from Kentucky, Colorado, and New Mexico, as well as that shipped, has been credited in the statistics to the State of origin. Production of finished fluorspar in 1951 comprised 73 percent acid-grade, 22.5 percent pelletized gravel, and 4.5 percent filter cake; the filter cake was sold to local producers for blending with fluxing gravel. The Ozark-Mahoning Co. was the largest producer of fluorspar in the United States in 1951.

The Rosiclare Lead & Fluorspar Mining Co. operated the Eureka-Deatherage, Geely, Hawkins, Hillside, Interstate, North Boundary, Pell, South Boundary-Recovery, and Rosiclare properties in 1951, but the Rosiclare and North Boundary were the chief producing mines of the company. The company also purchased finished fluorspar and milling ore from local producers. The ore produced and purchased is mill feed for the company heavy-medium, jig, and flotation mills. Production of finished fluorspar of all grades was 74 percent more than in 1950, and shipments were 35 percent greater.

Operations at the mine and flotation mill of Minerva Oil Co. were again at increased rates in 1951. Production of fluorspar flotation concentrates was 7 percent greater than in 1950, but shipments were 19 percent larger. Diesel-driven haulage trucks were introduced in

Digitized by Google

the east half of the mine. The Diesel-driven shovel continued in use about half time.

Throughout 1951 Frazer & Hettiger operated its flotation mill at Rosiclare on tailings from the Hillside mill-site.

Production at the Victory mine of Victory Fluorspar Mining Co. in 1951 tripled that in 1950.

At the Douglas mine in Pope County, operated by Hicks Creek Fluorspar Mining Co. and P. M. T. Mining Co., production in 1951 was 25 percent more than in 1950. The Redd mine operated by Redd Mining Co., Grandpier mine operated by Grandpier Mining Corp., and the Empire mine operated by Egyptian Mining Co.—all in Pope County—and the Baker mine operated by Golconda Illinois Mining Co., Inc., Jackson mine operated by Gibbons Mining Co., Knox mine operated by Knox Spar Co., Humm mine operated by C. C. Mackey, Rose Creek mine operated by S. C. Yingling, Dimick mine operated by Cullum Bros., Hamp mine operated by Trammel & Guard, and Pell mine operated by Thurmond Coal Co.—all in Hardin County—were the largest of the many smaller mines worked in Illinois in 1951.

Kentucky.—Production of finished fluorspar in Kentucky in 1951 dropped for the fourth consecutive year and was 63,700 short tons compared with 64,700 tons in 1950. However, the 1951 output includes 500 tons of finished fluorspar recovered from milling crude ore mined before 1951. Consequently, new production (expressed in terms of finished fluorspar) totaled 63,200 tons in 1951 compared with 63,600 tons in 1950. Shipments were 68,635 tons compared with 80,137 tons in 1950. Of the 1951 shipments, 18,234 tons was shipped to consumers by river or river-rail compared with 37,234 tons in 1950.

Production of fluorspar in Caldwell County in 1951 came chiefly from the Marble, Hughett, Williamson, and Schwenck mines.

The major part of the 1951 output in Crittenden County came from the Delhi-Babb, Pigmy, Davenport, Tabb No. 1, Ainsworth, Watkins-Settles, and Yandell No. 22 mines. Some of the remainder came from many smaller producing mines, but much was recovered from tailings from previous milling operations.

United States Steel Co. production and shipments of fluorspar in 1951 were 15 and 1.2 percent, respectively, smaller than in 1950. Output came from the Tabb No. 1 and Yandell No. 22 mines.

The Kentucky Fluor Spar Co. and affiliates shipped 19 percent more fluorspar and "fluorbarite" than in 1950. The company operates mills at Marion, Ky., and Rosiclare, Ill., and, through its mining division (Roberts & Frazer) operates the Carr mine in Livingston County, Ky. About 47 percent of the supply came from company mines in 1951. Most of it was furnished by the Empire, Blue Valley, Pell, Douglas, Humm, Grandpier, Baker, Dimick, Rose Creek, Wall, Jackson, and Knox mines in Illinois; Cox, Ainsworth, Williamson, and Watkins-Settles mines in Kentucky; the flotation mill of Minerva Oil Co.; and mines in Mexico. The Mexican fluorspar, which was used to raise the grade of locally purchased fluorspar, has not been included in the Kentucky statistics.

The heavy-medium mill of Inland Steel Co. near Marion treated purchased crude ore and concentrates recovered by washing tailings from the Keystone, Klondike, and other properties.

302512—54——38

Digitized by Google

Output of fluxing-gravel fluorspar at the Pigmy mine of the Pigmy Corp. (subsidiary of the Rosiclare Lead & Fluorspar Mining Co.) doubled that in 1950. However, less flotation concentrates was recovered from Pigmy pond fines at the flotation mill of Crider Bros. Fluorspar Co. for the Pigmy Corp. in 1951.

All of the supply of Delhi Fluorspar Corp. in 1951 was purchased from local producers and from Mexico; the Mexican fluorspar was blended with domestic. The Mexican fluorspar so blended and shipped has not been included in Kentucky statistics. Total sales were 24 percent more in 1951 than in 1950.

L. Conyer, who depends on purchased ore from local producers for his supply, shipped 41 percent more fluorspar in 1951 than in 1950.

B. E. Clement, who also depends on purchased fluorspar from local mines, shipped 2.5 times more fluorspar than in 1950.

Crider Bros. Fluorspar Co. and its successor (J. Willis Crider Fluorspar Co.) operated the Marble mine in Caldwell County, reclaimed some fluorspar from the Blue and Haffaw dumps, and purchased fluorspar from local producers, Arizona, Tennessee, and Mexico. The company also operates gravity-concentrating and flotation mills. Sales of fluorspar doubled those in 1950. The company produced flotation concentrates on a custom basis for Pigmy Corp., Inland Steel Co., and United States Steel Co.

C & L Fluorspar operated its flotation mill in 1951 on tailings and purchased fluorspar from local producers, chiefly Minerva Oil Co., Hicks Creek Fluorspar Mining Co., and Cardinal Fluorspar Co. Total sales by C & L Fluorspar Co. were 39 percent more than in 1950. It sold its flotation mill to Pennsylvania Salt Manufacturing Co.

The Davenport mine was reopened in 1951 by Davenport Mines, Inc., and the ore was treated in its heavy-medium mill. The mill was operated on accumulated dump piles in 1950. Output of concentrates was 2.3 times greater than in 1950.

The Marimex Fluorspar Co., Inc., was organized late in 1951 to purchase and sell local and Mexican fluorspar.

The Pennsylvania Salt Manufacturing Co. acquired two flotation mills near Marion during 1951 and produced a small quantity of flotation concentrates in December. It also purchased about 70,000 tons of tailings averaging about 29 percent calcium fluoride from C & L Fluorspar Co.

In Livingston County production of fluorspar in 1951 came chiefly from the Carr mine and from reworking the Klondike tailings.

No fluorspar was mined in the Central Kentucky fluorspar district in 1951.

Nevada.—Shipments of fluorspar from Nevada decreased in 1951.

The chief producing mine in Nevada in 1951 was the Daisy in Nye County, operated by J. Irving Crowell, Jr. Small outputs of fluorspar were made at the Baxter mine in Mineral County by Fallon Fluorspar Mines, Inc., at the Cirac Revenue Group in Churchill County by C. P. Cirac, and at a prospect near Grantsville, Nye County, by Gant & Pugh. The Baxter mine, which was purchased late in 1950 by H. W. Gould & Co. (Fallon Fluorspar Mines, Inc.), was sold to Kaiser Aluminum & Chemical Co., which plans to build a flotation mill to treat the ore. H. W. Gould & Co. purchased a two-thirds interest in the Nyco fluorspar prospect in Nye County.

Digitized by Google

New Mexico.—New Mexico produced 24,300 short tons of finished fluorspar in 1951, a 22-percent gain over 1950. This output includes 3,200 tons of finished fluorspar recovered from milling crude ore mined before 1951; consequently, new production (expressed in terms of finished fluorspar) totaled 21,100 tons in 1951 compared with 16,300 tons in 1950. The 1951 output came from Dona Ana, Grant, Lincoln, Luna, Rio Arriba, Sierra, and Valencia Counties. The Zuñi mines in Valencia County, Shrine mine in Grant County, Greenleaf and White Eagle mines in Luna County, and Universal and Blue Jacket mines in Sierra County supplied about 88 percent of the fluorspar produced in New Mexico in 1951. Most of the remainder came from many mines and prospects, chiefly the Clum, Florida, Greenspar, Sadler No. 2, Nakaye, Linda Vista, and Mirabal.

The flotation mill of General Chemical Division, Allied Chemical & Dye Corp., at Deming produced 6 percent more concentrates in 1951 than in 1950. The mill feed comprised ore from the company-operated Shrine mine in Grant County and Florida mine in Luna County and purchased ore from local mines, chiefly the Greenleaf and Sadler No. 2 mines in Luna County and the Clum and Linda Vista mines in Grant County.

The flotation mill of Zuñi Milling Co. at Los Lunas produced 74 percent more fluorspar in 1951 than in 1950. The mill feed comprised ore chiefly from the company mines near Grants in Valencia County and purchased ore chiefly from the Universal, Blue Jacket, Nakaye, and Cox mines in Sierra County, the Lone Star mine near Benson, Cochise County, Ariz., and ore from Mexican mines. The concentrate recovered from ore from the Lone Star mine, as well as that shipped, has been credited to Arizona in the statistics. The concentrate recovered from Mexican ore, as well as that shipped, has not been included in the statistics on production and shipments. The Zuñi Milling Co. milled 1,007 tons of ore from the White Eagle mine for the Ozark-Mahoning Co.

Tennessee.—The Tennessee output of fluorspar in 1951 was 240 short tons compared with none in 1950.

In 1951 about 100 tons of commercial calcium fluoride was produced by the Tennessee Valley Authority as a byproduct of a fluorine-recovery system under development at TVA's experimental fused-tricalcium phosphate fertilizer plant near Columbia. The product contains 78 to 84 percent calcium fluoride, 2 to 2.6 percent silica, and 1.3 to 2.2 percent sulfur.

Utah.—Finished fluorspar produced in Utah in 1951 totaled 16,109 short tons, compared with 20,626 tons in 1950. The production came from Juab County near Delta, where Bell Hill Mining Co., Carlson & Schmidt, Chesley & Black, T. A. Claridge, E. D. Harris, Fred Staats et al., and Willden Bros. operated.

MILLING

Output of flotation concentrates from domestic ore totaled 183,624 short tons in 1951 compared with 146,631 tons in 1950. In addition, 1,348 tons of flotation concentrates were recovered from milling 1,766 tons of Mexican ore at a plant in the United States.

The Ozark-Mahoning Co., which operates flotation plants at Rosiclare, Ill., and Jamestown, Colo., began to construct a flotation

Digitized by Google

plant at Northgate, Colo. It was to have a capacity of 25,000 tons of concentrates annually and to be completed about July 1, 1952.

At the flotation plant of Minerva Oil Co., near Cave in Rock, Ill., a new screen to increase storage in the mill bin and a new ball mill for a third stage of grinding primary ore were added. As a consequence, the over-all grind is finer than before and has resulted in improved grades of zinc concentrate and improved recovery of fluorspar.

Butler & Moodie installed a washing plant near Mullikin, Livingston County, Ky., for treating ore in old dumps at the Klondike mine. The washed ore recovered is hauled to the heavy-medium mill of Inland Steel Co. near Marion, Ky., where it is beneficiated further.

The flotation mill built in 1944 by Chamac Mining Co. to treat ore from the Chamac fluorspar deposit near Myers Cove, Lemhi County, Idaho, was acquired by Fluorspar Mines, Inc., and rehabilitated; production of acid-grade concentrates was begun August 1.

Reynolds Mining Corp. purchased the flotation mill of Fluorspar, Inc., near Salida, Colo. The mill, which had been under construction, was completed and put into operation in December.

The recovery of fluorspar by the treatment of mine waste rock in a heavy-medium mill at the Davenport mine 10 miles southwest of Marion, Ky., has been described.[1] The nodulization and pelletization of fluorspar flotation concentrates have also been described.[2]

PRICES

Metallurgical-grade fluorspar containing 70 percent or more effective calcium fluoride was quoted at $41 a short ton f. o. b. Illinois-Kentucky mines until February 1, when it was advanced to $43; that containing 60 percent or less effective calcium fluoride was increased $3 a ton to $41, but pellets were quoted at $34 throughout the year. Imported metallurgical-grade fluorspar was quoted throughout 1951 at $36 to $40 a short ton at Atlantic Seaboard, duty paid. Acid-grade fluorspar containing a minumum of 97 percent calcium fluoride was quoted at $50 a short ton f. o. b. Illinois mines until October 1, when it was advanced to $60. On October 1 acid-grade fluorspar was quoted at $65 a short ton f. o. b. Los Lunas, N. Mex.

The average selling price of all grades of domestic fluorspar shipped in 1951 was $41.41 a short ton—a new peak—compared with $35.22 in 1950.

Price Control.—Throughout 1951 the price of domestic metallurgical-grade fluorspar was controlled by provisions of the General Ceiling Price Regulation, which froze prices at the highest charged between December 19, 1950, and January 25, 1951. The prices for acid-grade and imported metallurgical-grade were likewise frozen until August 10 and September 6, respectively; however, on August 10 acid-grade fluorspar was exempted from price control, and on September 6 sellers of imported fluorspar were permitted to add increases in landed costs.

FOREIGN TRADE [3]

Imports.—A new record of 181,275 short tons of fluorspar was imported into the United States in 1951, a 10-percent gain over 1950, the former record year. Of the 1951 total, 52,991 tons contained over 97 percent calcium fluoride and 128,284 tons was of lower grade. Imports in 1951 were valued at $4,110,081.[4]

TABLE 10.—Fluorspar imported for consumption in the United States in 1951, by country and customs district

[1] Reported as Netherlands, but is believed to have originated in Germany.

The higher-grade fluorspar averaged $35.84 a ton and the lower-grade $17.24. As a consequence of abrogation of the reciprocal trade agreement between the United States and Mexico on December 31, 1950, the duty on fluorspar containing not over 97 percent calcium fluoride reverted to $7.50 a short ton and the duty on higher-grade

[3] Figures on imports and exports (unless otherwise indicated) compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

[4] Values are at country of origin. The cost to consumers in the United States also includes ocean freight, import duties, etc.

Digitized by Google

to $5 a short ton. However, effective June 7, 1951, the rate of duty on fluorspar containing over 97 percent calcium fluoride was lowered to $1.87½ a short ton under the Torquay Agreement.

The bulk of the fluorspar received in the United States in 1951 was for use by domestic consumers; however, a substantial tonnage of of acid-grade fluorspar was delivered to the National Stockpile.

In 1951, 8,788 tons of Mexican fluorspar was blended with fluxing-gravel fluorspar from the Illinois-Kentucky district. The Mexican fluorspar so blended has been excluded from the statistics on shipments from mines in the United States and included in the figures on imports.

Table 11, compiled from data supplied to the Bureau of Mines by importers and domestic companies milling foreign fluorspar, shows the quantities of imported fluorspar delivered to consumers in the United States. The quantities are based on the actual outturn weights and represent the finished fluorspar recovered from milling and drying foreign ore rather than the ore milled or concentrates dried.

Exports.—Fluorspar producers reported exports of 1,148 short tons of fluorspar valued at $51,809 in 1951 compared with 728 tons valued at $29,746 in 1950. The exports comprised 61 tons of metallurgical-grade to Canada and 20 tons to Venezuela; and 673 tons of flotation concentrates to Canada, 3 tons to Colombia, 24 tons to Chile, 320 tons to Peru, 44 tons to Mexico, and 3 tons to the Philippines. In addition to the fluorspar exported by producers in 1951, dealers exported 20 tons to Chile and 5 tons to Uruguay.

WORLD REVIEW

Canada.—According to the Dominion Bureau of Statistics, production of fluorspar in Canada was 78,870 metric tons [5] in 1951 compared with 58,253 tons in 1950.

The St. Lawrence Corp. of Newfoundland, Ltd., and Newfoundland Fluorspar, Ltd., both in the Province of Newfoundland, are the chief Canadian producers of fluorspar. There is a comparatively small production in the Province of Ontario.

The St. Lawrence Corp. of Newfoundland, Ltd., has a gravity-concentration mill and a flotation mill in Newfoundland for treating the ore from its several mines; a subsidiary, St. Lawrence Fluorspar, Inc., has a plant at Wilmington, Del., for drying the flotation concentrate. Shipments by the St. Lawrence Corp. of Newfoundland, Ltd., totaled 29,421 short tons in 1951 (18,125 tons in 1950)—15,891 tons of acid-grade filter cake and 13,530 tons of fluxing-gravel fluorspar.

[3] Estimate.
[4] Revised figure.

Newfoundland Fluorspar, Ltd., has two mines and ships crushed fluorspar principally to Arvida, Quebec, where the Aluminum Co. of Canada, Ltd., has a flotation plant.

France.—Production of fluorspar in France in 1951—50,000 metric tons—was the largest since 1939 and an increase of 41 percent over 1950.

[5] 1 metric ton is equivalent to 1.10231 short tons.

Digitized by Google

Germany.—Before World War II Germany was a leading producer and exporter of fluorspar; in fact, 1939 output was 161,963 metric tons. Until the outbreak of war exports were maintained at 30,000 to 40,000 tons annually. Production in West Germany has ranged from 16,900 to 50,000 tons during the 4 years 1946–49. Since 1950, however, Germany has shown much enterprise in regaining its former position as a producer and exporter. Production of fluorspar in West Germany was 92,520 and 143,741 metric tons, respectively, in 1950 and 1951. The United States was an important customer; imports of German fluorspar into the United States were 26,874 and 44,519 metric tons, respectively, in 1950 and 1951. In 1951 fluorspar was also exported to Austria, Australia, Belgium, Luxembourg, Denmark, Netherlands, Sweden, Poland, Switzerland, and Japan.

Italy.—Fluorspar production in Italy established a new record in 1951 and was 40,838 metric tons compared with 31,611 tons in 1950 and the former high of 40,635 tons in 1948. The United States was an important customer; imports of Italian fluorspar into the United States were 10,708 and 8,820 metric tons, respectively, in 1951 and 1950. Substantial shipments were also made to Japan in 1951.

Mexico.—Chiefly as a result of record demand for fluorspar in the United States—the principal market for Mexican fluorspar—production (as measured by exports) in Mexico was 1.7 percent greater than in 1950, or 66,761 metric tons. About 2,200 tons of Mexican fluorspar is used at local metallurgical plants, and some is exported to Canada. Imports of Mexican fluorspar into the United States were 58,082 and 66,270 metric tons, respectively, in 1951 and 1950. Several American producers and consumers have been greatly interested in recent discoveries of important deposits of fluorspar in Chihuahua and Coahuila. Because of the nearness of these deposits to the American border and their favorable location for truck transportation, they promise to make a major contribution to the United States supply. A flotation mill to serve the General Escobedo mine about 35 miles northwest of Taxco was completed at Zacualpan by Fluorspar Tolteca, S. A., in 1951.

Spain.—Chiefly as a result of sustained demand in the United States and a greater demand in Europe and Japan, fluorspar output in Spain increased to 54,789 metric tons in 1951 from 32,669 tons in 1950. Consumption of fluorspar in Spain is small; consequently, the industry depends largely on the export market for survival. The United States and Japan were the chief markets in 1951; imports of Spanish fluorspar into the United States were 29,814 short tons in 1951 compared with 32,025 tons in 1950. The imports into the United States in 1951 comprised 10,508 metric tons of acid-grade filter cake, chiefly from the flotation mill serving the Osor mine in the Gerona district, and 19,306 tons of metallurgical-grade fluorspar, chiefly from the Caravia and Collada mines in Asturias. About 20,000 tons is believed to have been exported to Japan in 1951.

The largest producers of fluorspar in Spain in 1951 were Fluoruros, S. A., which operated the Collada and Caravia mines in the Province of Oviedo, and Minerales y Productos Derivados, S. A., which operates the Osor mine in the Gerona district. Fluoruros, S. A., the largest producer of metallurgical-grade fluorspar in Spain, installed a washing plant and a flotation unit in 1951 and began to produce acid-grade

Digitized by Google

concentrates at the rate of 500 tons a month. About 800 tons of acid-grade filter cake was exported to the United States in December 1951. Minerales y Productos Derivados, S. A., is the largest producer of acid-grade flotation concentrates in Spain.

South-West Africa.—The South African Iron & Steel Industrial Corp., Ltd. (Iscor), is planning to bring its fluorspar property into production at a rate of 4,000 tons of concentrates a month and to export all surplus over the Union's present requirements of 10,000 tons annually. However, no appropriation has yet been made for the proposed operation. The fluorspar deposit is on Farm Okorusu some 40 miles northwest of Otjiwarongo, 14 miles west of the narrow-gage railway to Usakos and Walvia Bay. It has been held by Iscor since 1946 under a bond and lease covering approximately 2 square miles. Considerable diamond drilling and underground development have been done, and assured and probable reserves of 2,500,000 and 500,000 tons, respectively, carrying 60 percent CaF_2, 7 percent apatite, and 20 percent SiO_2 have been determined. Production may be expected by 1954.[6]

The Tsumeb Corp. holds a number of claims surrounding Iscor's deposits on which it has developed approximately 250,000 tons of excellent-grade ore and about 1,000,000 tons of 25-percent CaF_2 ore. Because of the interest being shown in fluorspar, the Tsumeb Corp. is planning a new study of its fluorspar deposits with the hope of developing more extensive reserves.[7]

CRYOLITE

The only known commercial-size deposit of natural cryolite is at Ivigtut, Greenland, where this unique mineral is mined.

Synthetic cryolite was manufactured in the United States in 1951 by the Aluminum Ore Co. at East St. Louis, Ill., and the Reynolds Metals Co. at Bauxite (Hurricane Creek), Ark.

Cryolite is used principally in the aluminum industry, where it acts as the electrolyte in reducing alumina to the metal. Smaller quantities are used chiefly in abrasives, insecticides, glass, and enamel.

Imports of natural and artificial cryolite into the United States totaled 34,688 long tons valued at $2,190,123 in 1951 compared with 15,298 tons valued at $978,175 in 1950; of these, 34,531 tons came from Greenland, 98 tons from Denmark, and 59 tons from Germany.

Exports of cryolite from the United States were 1,426 long tons valued at $317,413 in 1951 compared with 1,850 tons valued at $404,931 in 1950. Of the 1951 exports, 1,300 tons went to Canada, 77 tons to Mexico, 23 tons to Union of South Africa, and the remainder to Argentina, Brazil, Chile, Colombia, Philippines, and Surinam.

The preparation and use of natural cryolite were described in a report issued several years ago.[8]

Fuel Briquets and Packaged Fuel[1]

By J. A. Corgan and Golden V. Chiriaco

GENERAL SUMMARY

OUTPUT of fuel briquets and packaged fuel in 1951 totaled 2,387,219 and 119,535 net tons, respectively, 14- and 12-percent decreases from 1950. Briquets were shipped to 36 States and the District of Columbia in 1951. Exports, virtually all destined to Canada, totaled 168,780 tons; all of the 123 tons imported came from Canada.

Bituminous coal and Pennsylvania anthracite were the principal raw fuels employed manufacturing fuel briquets in 1951, and asphaltic binders were used exclusively. Bituminous coal and petroleum coke were the principal raw fuels used in making packaged fuel, and asphalt, starch, and a small amount of cement were employed as binders.

The fuel-briquetting industry consists of plants producing a small, hard, pillow briquet suitable for shipment. The packaged-fuel industry consists of plants producing 3- to 4-inch, more or less friable cubes wrapped (six to eight to the package) in sturdy paper, suitable for local consumption but not as a rule for transportation over long distances.

FUEL BRIQUETS

Pertinent data on the fuel-briquetting industry from 1947 to 1951 are summarized in table 1. Production, by regions, from 1919 to 1951 is illustrated in figure 1.

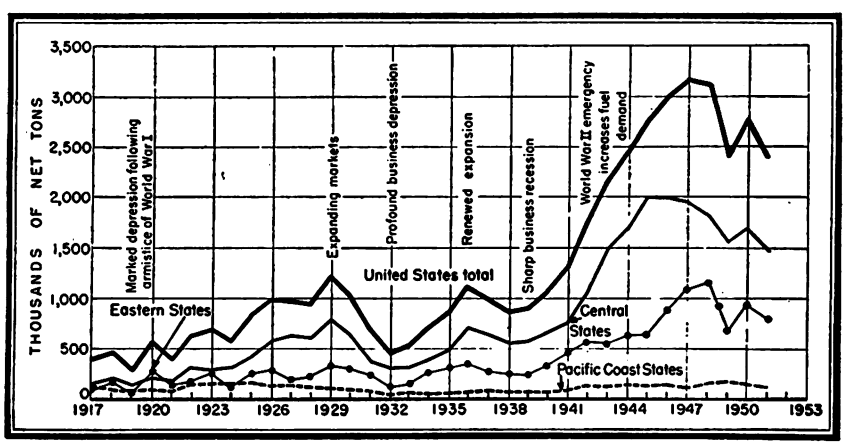

FIGURE 1.—Production of fuel briquets in the United States, 1917–51, by regions.

[1] Excludes briquets made from charcoal, wood scrap, and fruit pits, which are not included in Bureau of Mines surveys.

[4] Revised figure.

DOMESTIC PRODUCTION

The 14-percent decrease in the output of fuel briquets in 1951, when a total of 2,387,219 net tons was produced, can be attributed largely to competition of fuel oil and natural gas.

As shown in table 2, 28 plants produced briquets in 1951.[2] Eleven States contributed to the 1951 production, the Central States, with 20 plants, accounting for 61 percent of the total. Wisconsin, with 10 plants and about 42 percent of the national output, was the largest individual fuel-briquet-producing State. West Virginia followed with two plants, and Pennsylvania ranked third with four plants operating. Other producing States, in order of output, were: Missouri, Oregon, Illinois, Indiana, North Dakota, Michigan, Arkansas, and Nebraska.

TABLE 2.—Production of fuel briquets in the United States, 1950–51

1950	31	4,455,000	2,770,020	62.2
1951:				
Capacity of—				
Less than 25,000 tons	4	42,180	18,703	44.3
25,000 to less than 100,000	7	384,000	165,034	43.0
100,000 to less than 200,000	8	870,500	420,569	48.3
200,000 to less than 400,000	6	1,610,000	956,491	59.4
400,000 or more	3	1,500,000	826,422	55.1
Total	28	4,406,680	2,387,219	54.2
Production of—				
Less than 5,000 tons	3	22,180	7,453	33.6
5,000 to less than 10,000	2	140,000	14,626	10.4
10,000 to less than 25,000	2	70,000	28,350	40.5
25,000 to less than 100,000	13	1,264,500	644,906	51.0
100,000 or more	8	2,910,000	1,691,884	58.1
Total	28	4,406,680	2,387,219	54.2

The total value of the 1951 production, $27,454,638, reflects a decrease of about 14 percent from the value of $32,039,379 reported for 1950.

Capacity.—The rate of production in 1951 (54 percent of capacity) was considerably lower than in 1950, when the industry produced at 62 percent of capacity (*see* table 3). Nine plants, with an annual capacity of 200,000 tons or more each, furnished 1,782,913 tons or about 75 percent of the total production, utilizing 57 percent of their combined capacity. Seventeen plants, with an annual capacity of 100,000 tons or more each, supplied 92 percent of the total production in 1951, utilizing 55 percent of their combined capacity.

Raw Fuels.—Bituminous coal was the principal raw fuel used in manufacturing fuel briquets in 1951, followed in order by Pennsylvania anthracite and petroleum coke. These accounted for 90 percent of the raw fuels used. Residual carbon from the manufacture of oil gas, anthracite other than Pennsylvania anthracite, semianthracite, and lignite char also were used as raw fuels. Yard screenings used at 12 plants were the source of 15 percent of all raw fuels.

Residual carbon from manufacture of oil gas	2	126,675					
Petroleum coke	4	144,050					
Total	[1] 28	2,240,677	Total	28	332,513	1,908,164	2,240,677

[1] A number of plants used more than 1 kind of raw fuel; hence, the sum of the plants is greater than the actual number of plants active (28) in 1951.

Pennsylvania anthracite was used extensively, either alone or in combination with bituminous coal, in Pennsylvania and Wisconsin. Large quantities of bituminous coal were used widely in the Eastern and Central States. Residual carbon from oil gas was the only raw material used in the Pacific Coast States.

Binders.—Asphaltic binders were utilized exclusively in making briquets in the United States in 1951, when 26 operators used 146,542 net tons. Two operators employed no binder. The percentage of binder in the briquets (by weight) ranged generally from about 5 to 9 percent. Eleven plants (producing 57 percent of the 1951 output) used binders representing about 7 percent of the weight of the briquets. Eight plants (supplying 32 percent of the production) used binders representing about 6 percent of the weight of the briquets; four plants used binders representing 8 to 9 percent of the weight of the briquets, and the remaining three plants less than 6 percent.

SHIPMENTS

Weight and Shape.—In 1951 briquets ranged in weight from 1⅞ to 20 ounces. Pillow shapes, all under 5 ounces except for an 11-ounce bituminous high-volatile pillow, were made at 25 plants and represented 77 percent of the total production; 2½-ounce cylindrical (barrel-shaped) and 18- and 20-ounce cubes supplied 23 percent of the total production.

In addition to the 2,174,599 tons of fuel briquets shipped to 36 States and the District of Columbia in 1951, 168,676 tons were exported to Canada. Wisconsin, Minnesota, Missouri, and Michigan received 1,245,544 tons of the total briquets shipped. The difference between production in 1951 (2,387,219 tons) and shipments within the United States (2,174,599 tons), or 212,620 tons, represents exports, briquets used at plants for power or heat, and changes in producers' stocks. Briquets are used almost entirely for space heating, but in 1951 operators reported 8,073 tons used for power or heat at their plants.

Of the 2,373,548 tons of fuel briquets reported by producers as shipped in 1951 (domestic and foreign) about 92 percent was destined to 36 States and the District of Columbia; 77 percent of the total shipments moved by rail and 23 percent by truck or scow. In the Eastern States about 97 percent was shipped by rail and 3 percent by truck; in the Central States 69 percent moved by rail and 31 percent, by truck; and in the Pacific Coast States about 46 percent moved by rail and 54 percent by truck and scow.

[1] Includes shipments outside the United States, as reported by producers (differs somewhat from export statistics).
[2] Includes quantities shipped by scow.
[3] An additional 11,737 tons was used by 4 producers as fuel at their plants in 1950 and 8,073 tons by 3 producers in 1951.

PRICES

Although the average value per ton of briquets (f. o. b. plant) produced in the Eastern States in 1951 showed a slight increase from 1950 (about 3 percent), the average per ton values for the Central and Pacific Coast States continued the downward trend began in 1950, reflecting decreases from 1950 of about 1 percent and 11 percent, respectively (*see* table 1). Gross realization per ton (f. o. b. plant) varies greatly because of the different local conditions under which briquets are made. In the Eastern States briquets are made relatively near the coal fields; hence the cost of raw material does not involve large freight charges, and the f. o. b. plant price is relatively low. In the Central States briquets generally are made at plants great distances from the original source of coal; consequently, raw-fuel costs at these plants include a considerable freight charge, which is reflected in higher prices per ton f. o. b. plant. The highest plant values are shown in the Pacific Coast States, where the raw fuel used is residual carbon from the manufacture of oil gas.

These f. o. b. plant values vary considerably from the prices paid for briquets by consumers, as retail prices include transportation costs and retail dealers' margins. Information on retail prices of fuel briquets for selected cities may be obtained from the Bureau of Labor Statistics, United States Department of Labor, Washington 25, D. C.

FOREIGN TRADE [3]

Imports of fuel briquets into the United States reached a peak of 123,593 net tons in 1926, when a strike during the winter of 1925–26 in the Pennsylvania anthracite fields created a shortage of fuels in this country. Imports have been negligible since 1941, amounting to only a few hundred tons a year; in 1951, 123 tons was imported, all from Canada.

In 1951 exports of fuel briquets, virtually all of which were destined to Canada, totaled 168,780 tons, a 4-percent decrease from 1950. The value of 1951 exports was $2,389,657, a 9-percent decrease from 1950.

[3] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

DOMESTIC PRODUCTION

In 1951, 53 plants operated in the United States as compared with 54 plants in 1950 and produced 119,535 net tons of packaged fuel

Digitized by Google

valued at $2,169,539, a decrease of 12 percent in tonnage and 11 percent in value from the preceding year. Michigan, Wisconsin, and Ohio, in the order named, were the three largest producing States and supplied about 69 percent of the 1951 output. The average value per net ton (f. o. b. plant) of packaged fuel increased consistently in the Central States from 1947 through 1951. Except for a slight drop in 1950, the average value per ton in the Eastern States increased steadily from 1947 through 1951 (*see* table 9). Proceeds received by the manufacturers are equivalent to cost of coal at the mine, freight to factory, direct and indirect manufacturing cost, and profit. For this reason, the values may vary greatly from plant to plant, depending on the local conditions under which the product is manufactured. Production of packaged fuel, by States, for 1950–51 is shown in table 10.

TABLE 10.—Production of packaged fuel in the United States, 1950–51, by States

State	1950			1951		
	Plants	Net tons	Value	Plants	Net tons	Value

Total	54	135,682	2,430,847	53	119,535	2,169,539

[1] Comprises 2 plants in Virginia and 1 plant each in Illinois, Iowa, Kentucky, Missouri, and Nebraska.
[2] Comprises 2 plants each in Virginia and Illinois and 1 plant each in Iowa, Kentucky, Missouri, and Nebraska.

Number of Plants.—Of the 53 plants producing packaged fuel in 1951,[6] 17 Michigan plants furnished 31 percent of the total output, 7 plants in Wisconsin 22 percent, and 14 plants in Ohio 15 percent.

Capacity of Plants.—Table 11 gives comparative data on capacity and production for 1947 to 1951 as reported by packaged-fuel operations active in those years. In 1951, 13 plants with a capacity of 5,000 tons or more, operating at 49 percent of their combined capacity, produced 91,938 tons of packaged fuel or 77 percent of the total 1951 output. Forty plants, each with an annual capacity under 5,000 tons, produced 27,597 tons (23 percent of the total production), utilizing about 31 percent of their combined capacity.

Raw Fuels.—Five kinds of raw fuel were employed in manufacturing packaged fuel in 1951. Bituminous low-volatile coal (used at 48 plants, either alone or in combination with other fuels) comprised 86 percent of the total raw fuel used. Small quantities of bituminous high-volatile coal, Pennsylvania anthracite, semianthracite, and petroleum coke also were consumed in manufacturing packaged fuel in 1951.

[6] *See* footnote 2.

Less than 1,000	31	59,410	11,450	19.3
1,000 to less than 3,000	15	69,600	25,961	37.3
3,000 to less than 5,000	1	40,000	23,309	58.3
5,000 to less than 10,000	3			
10,000 to less than 30,000	3	108,000	58,815	54.5
Total	53	277,010	119,535	43.2

Yard screenings were used exclusively at 30 plants to produce 21 percent of the total output; raw fuels other than yard screenings were used exclusively at 10 plants to manufacture 35 percent; and screenings and other raw fuels combined were used at 13 plants to produce 44 percent of the total 1951 production.

TABLE 12.—Raw fuels used in making packaged fuel in the United States, 1951

Type of raw fuel used	Plants using	Net tons used	Source of raw fuel used	Plants using	Net tons used		
					Yard screenings	Other raw fuels	Total
Bituminous low-volatile coal	48	100,937	Yard screenings exclusively (from own or other yards)	30	24,938	--------	24,938
Bituminous high-volatile coal	4	3,946	Raw fuels (other than yard screenings) exclusively	10	--------	39,471	39,471
Pennsylvania anthracite	--------	--------	Both yard screenings and other raw fuels	13	19,435	32,987	52,422
Semianthracite	2	2,695					
Petroleum coke	5	9,253					
Total	[1] 53	116,831	Total	53	44,373	72,458	116,831

[1] A number of plants used more than 1 kind of raw fuel; hence, the sum of the plants above is greater than the actual number of plants active (53) in 1951.

Binders.—Starch totaling 593 tons (an average of about 14 pounds per ton of packaged fuel produced) was the principal binder employed at 49 plants producing about 73 percent of the total 1951 output. Asphalt and cement were used exclusively at a few of the plants. Table 13 gives details on binders employed in manufacturing packaged fuel in 1948–51.

Total	[1] 62	100.0	[1] 57	100.0	54	100.0	53	100.0

[1] 1 plant making 2 types of packaged fuel used starch binder for 1 and asphalt and starch for the other; hence, the sum of the items shown exceeds the number of active plants.

SHIPMENTS

Sales of packaged fuel in 1951 totaled 119,840 net tons, of which 98,324 tons (82 percent) was listed as local sales (by truck) and 21,516 tons (about 18 percent) was reported as other than local sales. Of the 21,516 tons shipped outside the local area, 13,566 tons (about 63 percent) went by truck and 7,950 tons (37 percent) by rail.

TABLE 14.—Shipments of packaged fuel in the United States, 1947–51, by method of transportation, in net tons

Year	Shipped by truck			Shipped by rail	Total

[1] Includes sales both called for and delivered.

TECHNOLOGY

The Bureau of Mines conducted an investigation to determine the combustion characteristics of packaged fuels made of high-volatile and low-volatile bituminous coals, and the results were published in Report of Investigations 4797.[4] In this investigation, particular attention was given to the smoke-producing properties of the packaged fuels, because of the increasing demands for reduction of smoke from hand-fired domestic-heating furnaces.

[4] Myers, J. W., and Corey, R. C., Combustion Characteristics and Physical Properties of Packaged Fuels Containing Bituminous Coals: Bureau of Mines Rep. of Investigations 4797, 1951, 30 pp.

Digitized by Google

The Anthracite Institute continued to make briquets from fine sizes of anthracite by extrusion and coking in a continuous shaft. The institute hopes that the product will have application as a fuel for cupolas and blast furnaces.

The Natural Resources Research Institute at the University of Wyoming has done considerable detailed research on matters relating to briquetting various kinds of coals. The institute sponsored the first briquetting conference at Laramie, Wyo., in June 1949, and a second briquetting conference was held at Superior, Wis., in August 1951. The proceedings of the 1951 conference were published in University of Wyoming Information Circular 5.[5]

The papers presented related to the position of briquets in the energy and fuels markets, briquetting of coal in Canada and other foreign countries, briquetting machinery, binders, the drying of coal for briquets, etc. The institute has conducted studies on briquetting low-rank western coals, drying and briquetting high-moisture coals, and use of special binders in briquetting.

WORLD PRODUCTION

As indicated in table 15, world production of fuel briquets increased substantially in 1951. Virtually all countries shared in this increase; however, the United States was one country that showed a marked decline in output. This drop in United States production can be attributed primarily to competition from other space-heating fuels, which were in ample supply. In 1951, as in former years, Germany was the world's largest producer of fuel briquets.

Gem Stones

By W. F. Foshag,[1] George Switzer,[1] and Robert D. Thomson

GENERAL

DOMESTIC PRODUCTION

AS IN THE PAST, the United States continues to be an unimportant factor in world gem production. A wide variety of gems is produced but in small quantity. Gem mining is, and probably will continue to be, a minor industry.

Most gem-stone production in the United States results from the interest of thousands of amateur lapidaries, who pursue their hobby with great vigor and spend their vacations and weekends searching for materials suitable for cutting and polishing. Much of what they collect passes into the hands of numerous small mineral and lapidary supply dealers or roadside curio shops and changes hands through sale or exchange. The many varieties of quartz, such as agate, jasper, and petrified wood, are the chief materials produced in this way.

There are no large gem-mining companies in the United States. A few small companies operate certain deposits from time to time, such as turquoise, tourmaline, and jade, but they employ only a few miners. Since such a small percentage of the total gem production is mined on a commercial scale, no reliable statistics of the value of the domestic output of gems can be compiled. The value may approximate $400,000 to $500,000.

The many forms of quartz—chiefly the crypto-crystalline varieties—were produced in greatest quantity and value in 1951. Other gems produced, but in very much smaller quantity, were jade, kunzite, and turquoise, and a number of others in almost insignificant quantity. Of the producing States, California, Oregon, Texas, Washington, and Wyoming were the leaders.

Agate.—As far as could be ascertained, there was no appreciable change in agate production (including all varities of chalcedony) from that of 1950.

The Alpine-Big Bend area in Texas was one of the leading producers. A single locality near Alpine was reported to have yielded approximately 6,000 pounds of agate during the year, with an average value of 25 cents per pound.

Production from New Mexico was reported as essentially unchanged from the previous year.

---

[1] Smithsonian Institution, consulting mineralogist to Bureau of Mines.

Digitized by Google

Large quantities of agate also were found in California, Oregon, and Washington, with smaller quantities in Arizona, Montana, and Wyoming. Small quantities of all forms of chalcedonic quartz, such as agate, jasper, petrified wood, and chert, were collected in nearly every State. A small quantity of chrysoprase was said to have been recovered at Porterville, Calif.

Kunzite.—Renewed mining activity in the Pala district, San Diego County, Calif., in the years 1949–51 yielded important quantities of kunzite. In the Vandenberg mine pockets were struck in July and October 1951 which yielded about 150 pounds of kunzite, of which about 10 percent was fine gem quality. The larger of these two pockets contained material of exceptionally good color. The value of this find was estimated at about $16,000.

Jade.—The available supply of Wyoming nephrite jade continued to diminish. Material of good color was reportedly selling for $30 to $60 per pound. A new find was reported in Shirley Basin, north of Medicine Bow, yielding some material of good medium-green color, selling at $5 to $10 per pound.

In California some jade (nephrite) was found along the coast near Monterey, and some jadeite jade was collected at Clear Creek, San Benito County. No production was reported from the Porterville locality. Reports published in 1951 described the jade deposits in Marin, Monterey, and San Benito Counties, Calif.[2]

No production of nephrite jade was reported for the year from the Kobuk area, northwestern Alaska.

Turquoise.—Turquoise production continued to decline in the Southwest. There was no large-scale activity in any turquoise localities, although undoubtedly small quantities were produced from various mines in Nevada, Arizona, and Colorado.

Other Gem Stones.—No diamonds were produced from the Arkansas diamond mines in 1951.

The Barton Mines Corp., North Creek, N. Y., reported a 1951 production of 60 pounds of gem-quality garnet, valued at $85.

No sapphire was produced in Montana from the Yogo Gulch area. The Yogo Sapphire Mining Corp. was negotiating to buy all the properties of the British-owned New Mine Sapphire Syndicate and planned to open the mines if negotiations were successful.

No variscite was produced from the Fairfield, Utah, locality during 1951 because of litigation. A small quantity was obtained by collectors at Grantsville and Lucin, Utah, and a new variscite deposit was reported near Snowville, Box Elder County, Utah.

A number of good-size pieces (single pieces up to several hundred carats) of pale-blue topaz were recovered by collectors in Mason County, Tex. The Thomas Mountains, Utah, topaz locality was visited by many collectors, but no important production resulted.

Digitized by Google

Small quantities of tourmaline and morganite were produced in San Diego County, Calif., and some tourmaline and aquamarine in the various New England pegmatite localities, chiefly in Maine and New Hampshire.

Rose-quartz production from South Dakota was small. Some of the rock-crystal quartz from Arkansas undoubtedly went into the gem trade.

The total value of these miscellaneous gems probably was not more than a few hundred dollars.

CONSUMPTION AND USES

Business conditions in the jewelry industry remained essentially the same as in 1950. In general, sales were slow, particularly in the early months of the year, and even the traditional Christmas rush did not come up to the expectations of most retailers. Continuation of the Korean War eliminated any immediate chance of a reduction in the 20-percent excise tax on jewelry. This, plus continually rising living costs, caused a slump in the jewelry industry.

Again in 1951, the United States was the principal world market for diamonds. There was no significant change in the volume of diamonds sold by jewelers. Diamond jewelry sales represented about one-quarter of total jewelry sales of the typical dealer in 1951. Most jewelers had no trouble in obtaining an adequate supply of diamonds, although fine-quality stones in the larger sizes were said to be in short supply.

Fashion in Jewels.—During 1951 women continued to wear a large quantity of jewelry of conspicuous sizes. There was a steady rise in the production and use of baguette diamonds, as well as other fancy cuts, such as the pear and marquise. Large, emerald-cut diamonds were the most coveted solitaires, but because of their high price few could afford them.

Paris jewelry went to no extremes and made no radical departure in style. Leaf forms from many trees and shrubs inspired the designers. The scale continued large, but forms were light and airy.

Paris continued to set trends for the world of fashion in 1951, but three Italian cities—Rome, Florence, and Milan—also emerged as sources of inspiration. Since the Italian jewelry designers sometimes come from the ranks of painters, sculptors, and even architects, great diversity of artistic creation may be expected from this source.

IMPORTS [8]

Imports of gem stones, exclusive of industrial diamonds, in 1951, as reported by the United States Department of Commerce, totaled $129.3 million, compared with $118.5 million in 1950, an increase of about 9 percent. Diamonds were the more important, totaling $110.6 million (86 percent) of the total value of imports, with "cut but unset" representing 56 percent of the diamond imports.

[8] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

TECHNOLOGY

The emphasis in gem-stone research was on diamonds. The Diamond Research Laboratory of Johannesburg, Union of South Africa, sponsored and supported by Industrial Distributors (1946), Ltd., investigated many problems in mining and utilization of diamonds.

Articles published recently dealt with the investigation of the Slipper diamond, a 7.25-carat octahedron with a small included octahedron [4] and the luminescence of polished cleavage plates of diamond; [5] description of the unusual twinned tetrahedral diamonds from the Belgian Congo; [6] a fractographic study of the cleavage face of a 34½-carat diamond from the Premier mine, South Africa, which had a cleavage pattern partly characteristic of type I and partly of type II diamond; [7] description of the effects of treating diamonds in a cyclotron; [8] and measurement of the thermo conductivity of diamond, sapphire, and quartz.[9]

An excellent summary of the chief scientific and industrial development regarding diamonds that took place during 1951 was prepared by

P. Grodzinski and his associates and distributed by the Industrial Diamond Information Bureau, 32–34 Holborn Viaduct, London, E. C. 1.

In the field of colored gem stones, taaffeite, a pale mauve gem resembling spinel but chemically a beryllium magnesium-aluminum oxide, was described.[10]

DIAMONDS[11]

The year 1951 was another record-breaking year in the diamond industry. The value of diamonds sold through the Central Selling Organization, on behalf of South African and other producers, amounted to £65 million. Sale of diamonds produced in Brazil, British Guiana, and Venezuela raised the overall total to approximately £68 million, an increase of about 30 percent over 1950. A 15-percent increase in diamond prices in March 1951 brought sterling prices to full parity with dollar prices, which were in effect before the devaluation of sterling in 1949. The increased sales for 1951, however, are only partly attributable to this cause, also being influenced by increased production of rough diamonds through increased mining activity and better milling practices.

A sharp increase in sales of industrial diamonds featured the 1951 market. Sales by the Central Selling Organization were divided as follows:

Gem diamonds	£46, 780, 632
Industrial diamonds	18, 277, 333
	65, 057, 965

A new record also was set for world production of diamonds in 1951, with a total of 16,800,000 carats, compared with 15,250,000 carats in 1950.

Cutting.—The strong demand for gem diamonds continued unabated during 1951.

In spite of this high level of activity, the cutting industry continued to be plagued with unemployment, indicating a surplus of workers in the industry.

Means to eliminate the disparity in cutting costs, wages, and working hours in the various cutting centers was widely considered, but no uniform wage basis could be determined. Neither the efforts of the Netherlands and Belgian cutters and manufacturers to arrive at some satisfactory arrangement, nor the efforts of the Universal Alliance of Diamond Workers to work out an agreement with the German diamond workers' organization on time, tariffs, and apprenticeships, were successful.

Belgium continued to be the largest cutting center, followed by Germany, Netherlands, Israel, and the United States. Smaller cutting centers were in England, South Africa, France, India, Brazil, and Puerto Rico.

Digitized by Google

In the United States employment in the diamond-cutting industry reached a low level in 1951. During the year less than 50 percent of the enrolled members of the Diamond Workers Protective Union had steady employment, and work in the non-union shops was seasonal. High labor costs in the United States permitted only cutting of the larger and finer grade stones.

Imports.—Imports of gem-grade diamonds into the United States amounted to $110,563,000 in 1951 compared with $102,187,000 (revised) in 1950, an increase of slightly less than 1 percent. The United Kingdom furnished most of the rough or uncut and Belgium-Luxembourg most of the cut in 1951.

World Production.—Official figures on diamond production are not available for all countries, but the figures in the accompanying table are believed to be reasonably accurate. World production in 1951 (gems and industrials) is estimated to have been 16,800,000 metric carats, which compares with 15,250,000 carats for 1950, an increase of nearly 10 percent.

Belgian Congo was again the leading producer by weight, but only about 5 percent of the Belgian Congo production was of gem quality. South Africa, although producing much less by weight, lead in value owing to a higher percentage of gem stones.

TABLE 3.—World production of diamonds, 1948–51, by countries, in metric carats

[Including industrial diamonds]

Country	1948	1949	1950	1951
Africa:

Industrial Diamonds.—Details regarding imports, production, sales, and uses of industrial diamonds will be found in the Abrasive Materials chapter of this volume.

OTHER GEM STONES

The price of most gem stones other than diamonds continued to hold steady owing to a short supply of newly mined stones of fine quality.

Ceylon maintained its output of important quantities of a variety of gems, chiefly ruby, sapphire, chrysoberyl, spinel, garnet, zircon,

Digitized by Google

topaz, and tourmaline. The gems came from the alluvial gravels of the Ratnapura district. The gem mining was done by individuals or small companies, and no official production figures are available.

Australian opal production [12] for 1951 was valued at £65,474, an increase of £9,255 over that produced in 1950. Good-quality material was scarce. The Andamooka and Coober Pedy fields in South Australia were the main producing centers. The Hayricks mine in the Quilpie district was the only one operating in Queensland, and a few men worked intermittently at Lightning Ridge, New South Wales. The value of opal exports in 1951 amounted to £79,972, as compared with £40,040 in 1950. The United States was the largest buyer in both years.

Australian sapphire production [12] during 1951 was valued at £1,135, compared with £3,181 in 1950. Production, which amounted to 63 ounces, was chiefly from the areas of Rubyvale and Sapphire, Queensland. Three cutting plants were operated at the fields, and lapidaries in Brisbane and other cities cut Queensland sapphires for the local market and export. No export statistics are available.

Cultured-pearl production in Japan during 1951 amounted to 3,375 kilograms. Production had risen steadily from none in 1945 to 938 kilograms in 1948 and 2,625 kilograms in 1950. The 1951 export value of cultured pearls was $4,354,000. An interesting change took place in the export market after World War II. In 1938, 40 percent of the cultured-pearl exports went to the United States, while in 1951 the corresponding figure was 61 percent.

Production of emeralds in Colombia was reported by the Ministry of Development to be about 68,000 carats in 1951. This represents only the production of the Government-owned Muzo and Cosquez mines, which had been closed the last quarter of 1949 but were opened again during the latter part of 1951; production was, however, erratic. Production of the privately owned Chivor mine is not known. The Chivor Emerald Mines, Inc., the owner, went into bankruptcy in April 1951. Some production was continued by the workers, but all of the stones went into the black market. Despite this trouble, it was reported that a new vein was found at Chivor, and the emeralds produced were said to be the best quality ever taken from the mine.

Brazil continued to produce a large quantity of amethyst, aquamarine, citrine, topaz, and tourmaline and smaller quantities of chrysoberyl, andalusite, euclase, and other gems.

Gem-stone production in other well-known districts, such as Burma, Thailand, Mozambique, Madagascar, and India, apparently was small, and no official figures are available.

SYNTHETIC GEM STONES

Synthetic **Emerald.**—This synthetic gem, so far as known, is produced only by the Chatham Research Laboratories in San Francisco, Calif. Production in 1951 averaged 5,000 carats per month in crystals averaging 40 carats each. The total production of 60,000

[12] Australian Bureau of Mineral Resources, Geology and Geophysics, Australian Mineral Industry—1951: 1952, p. 165.

Digitized by Google

carats for the year was an increase of about 20 percent over 1950. Production was broken down as follows: 50 percent very low grade (opaque) but good color, 40 percent medium grade, and 10 percent fine gem quality. Retail prices of top-quality stones remained about the same at $90 to $120 per carat. Flawless stones over 2 carats in size were not produced.

Corundum and Spinel.—The year 1951 found conditions in the American synthetic gem industry at a very low ebb owing to recovery of the European industry after World War II, chiefly in Germany and France.

It was reported that one shop in the United States continued to cut synthetics on a large scale, by offering well-cut and well-sized stones at higher prices than the European goods but with the added advantage of good deliveries. Most of the material cut from American sources was for educational jewelry (for example, class rings), the most popular style being the buff-top flat back. Ruby-colored corundum predominated, the distribution being 70 percent ruby corundum and 30 percent blue spinel.

The sales of rough synthetic gem stones manufactured in the United States virtually vanished. European manufactured synthetic gem stones—principally from Germany—reached manufacturing jewelers directly rather than through the normal channels of gem-stone dealers. Thus, by obtaining their gem stones directly from Europe the manufacturing jewelers bypassed wholesalers and realized some price advantage.

There was some increase in the use of synthetic star rubies and sapphires in 1951 over 1950. Also, some synthetic stars of European manufacture were seen and at much lower prices than those made in the United States.

Synthetic Rutile (Titania).—During 1951 titania sales increased somewhat, with a greater number of manufacturing jewelers incorporating this stone in their designs. However, there had not been great popular acceptance of this material, and it had not become a serious threat to the diamond trade, as was at first feared by some.

Gold and Silver

By James E. Bell

GENERAL SUMMARY

MINE production of gold and silver in the United States in 1951 failed to maintain the gains made in the preceding year. The domestic output of recoverable gold was 17 percent less in 1951 than in 1950. Further, it was smaller than in any other year since 1894, with the exception of those in the period 1943–46. The decline was general in all of the principal gold-producing States and was due to various combinations of factors in different areas, including lack of labor, depletion of reserves at some properties, lower average gold content of base-metal ores mined in 1951, smaller output of base-metal ores containing gold because of strikes, and curtailment or abandonment of straight gold-mining operations owing to high costs and the fixed price of gold. The output of recoverable silver was 6 percent smaller in 1951 than in 1950 but higher than in any of the years 1944–49; however, it was less than in any other year since 1934. Lower output prevailed in most of the principal silver-producing States owing to a smaller production in some areas of base-metal ores containing silver and to a lower average silver content of base-metal ores mined in other areas.

South Dakota was the leading gold-producing State in 1951, followed in order by Utah and California, the same as in 1950. These three States, with Alaska, produced 74 percent of the United States total output. The South Dakota output was obtained almost entirely from gold ore mined at the Homestake property in Lawrence County; Utah gold was principally a byproduct of copper mining in the West Mountain (Bingham district); California yield came mainly from straight gold-mining operations, both lode and placer; and Alaska production was almost entirely from placer operations, mainly bucket-line dredging. Of the gold produced in 1951, 25 percent was recovered by placer methods, 34 percent by amalgamation and cyanidation, and 41 percent in smelting ores and concentrates.

Idaho continued its rank as the leading silver-producing State, followed by Utah, Montana, and Arizona, an order unchanged since 1943. These four States furnished 84 percent of the domestic silver production of 1951. The Idaho output was recovered largely from dry ores, but most of the output from the other three leading States was byproduct silver from ores mined principally for base metals. Nearly 99 percent of the total domestic silver production of 1951 was recovered in the treatment of ores and concentrates.

Production of gold outside the United States was moderately greater in 1951 than in the preceding year owing mostly to a higher (estimated) production in the U. S. S. R. In the Rand district of Union of South Africa a little less ore of slightly lower average grade was mined, but operating profits were down considerably because of rising costs;

Digitized by Google

however, the sale of some of the output at premium prices sustained the overall revenue to gold producers. Production of silver outside the United States in 1951 was slightly above that in 1950 due mostly to increases in Peru, West Germany, and South-West Africa. The world production rates of gold and silver in recent years have been far below prewar averages.

Two properties reached the production stage late in 1951 in the new gold district of the Orange Free State (Union of South Africa) 150 miles south-southwest of Johannesburg. Eleven other properties were in development in this field, and 4 were expected to go into production in 1952. Extensive exploratory drilling and development work have indicated that the new field has an ultimate gold-production potential comparable to that of the famous Rand district.

The United States Treasury continued to purchase gold at $35 per fine troy ounce in 1951 and to purchase silver mined domestically after July 1, 1946, at $0.9050505 per fine troy ounce. Late in September 1951 the International Monetary Fund bowed to demands by most gold-producing countries to relax its policy regarding the sale of gold at premium prices on the free market. The New York price of silver continued to represent the basis for most international transactions in silver; prices in 1951 ranged from a low of $0.8000 to a high of $0.9016 per troy ounce 0.999 fine, compared with $0.7175 and $0.8000 in 1950. Some silver was diverted from United States Treasury stocks to satisfy trade requirements. International trade in silver continued to be dominated by regulations of various governments. The London market was hampered by exchange regulations, and India continued its ban on imports and exports of silver; Mexico limited exports to current production. Demand for silver by governments for coinage was approximately 89 million ounces in 1951 compared with 42 million ounces in 1950.

The net outflow of gold from the United States that began in September 1949 continued almost without interruption through June 1951; however, the situation was reversed in July, with the result that the net 1951 loss in United States monetary stocks was slight. Continuing a trend resumed in 1946, the net inflow of silver into the United States was maintained in 1951; however, it was 9 percent below that of 1950.

PREMIUM PRICES FOR GOLD

Developments in transactions in gold at premium prices and in private hoarding of gold have been reported in the chapters on Gold and Silver of Minerals Yearbooks for the past several years.

In a statement issued on September 28, 1951, the International Monetary Fund yielded to growing pressure to permit the member gold-producing countries to form their own regulations for disposal of their gold at premium prices.

Most of the gold-producing countries reacted to the announcement of the IMF by giving permission to their gold producers to sell, with certain restrictions, part or all their current output at premium prices on the free market. Even before the announcement, the Union of South Africa had sold as much as 40 percent of its current gold production in the free market, and no radical change in the volume of supply from this source was anticipated. Southern Rhodesia and

the British Colonies of Gold Coast, Tanganyika, and Kenya announced permission to gold producers to sell up to 40 percent of their respective outputs on lines broadly similar to those adopted by South Africa. Canadian authorities allowed Canadian gold producers the choice of selling their production on the free market, or of selling at the IMF price with participation (if eligible) in subsidies under the Emergency Gold Mining Assistance Act. The Australian Government ruled that the entire current Australian gold output could be sold in the free market.

It was estimated that, following the changes in policy of the IMF, the potential supplies of gold available for premium-price sales might amount to as much as 12 million ounces in 1952, provided the free market could continue to pay an appreciable premium. It was also estimated that about one-third of this quantity would be absorbed by the European markets, one-third by the Middle East, and one-third by the Far East. As a result of the September announcement of the IMF, the price of gold in the European free markets declined from about $40 per ounce to between $38 and $39.

The action of September 28, 1951, of the IMF brought no change in policy of the United States Government on the premium market for gold. The legality of domestic trade and holding of gold in its natural state was established under section 19 of the Provisional Regulations of the Gold Reserve Act of 1934, in these terms:

> Gold in its natural state may be acquired, transported within the United States * * * without the necessity of holding a license therefor.

However, production that could qualify as "natural" gold, eligible for trading, was limited to placer gold recoverable without the use of quicksilver and to free lode gold recoverable from the ore mechanically or by washing.

Special canvasses were made by the Bureau of Mines during recent years to determine the quantity of domestic "natural" gold sold in the market at premium prices and the amount of the premiums. Most of the producers reported no such sales, and some of those reporting were unwilling to furnish data on quantities sold or premiums received. However, it has been estimated that, in recent years, "natural" gold containing approximately 25,000 ounces of fine gold reached the domestic premium market annually and that approximately 75 percent of this metal was mined in Alaska and most of the remainder in California; prices were reported to have averaged $39 to $40 an ounce in 1949.

DOMESTIC PRODUCTION

Production of gold and silver in the United States is measured at mines and refineries. Both measures are tabulated by States of origin, but there is a small annual variation between them, explained largely by time lag. Over a period of years, the deviations are found to be negligible. (*See* table 2.)

MINE PRODUCTION

Following the rescinding in mid-1945 of War Production Board Order L–208 that restricted gold mining in the United States during a period in World War II, recovery in domestic straight gold mining proceeded slowly because of high wages, difficulties in recruiting labor forces, high prices for equipment and supplies, depletion of reserves, and the fixed price of gold. Operations at base-metal mines that yield byproduct gold were suspended at times by strikes. Despite these adverse factors, gold production recovered considerably in 1946 and 1947. It turned downward slightly in 1948 and 1949, rose sharply in 1950, then declined below the 1949 level in 1951. However, in no postwar year has the gold-production rate reached even half the alltime peak of 1940.

Since the low point in silver output of recent years established in 1946, silver production increased in 1947 and 1948. It dropped moderately in 1949, rose sharply in 1950, then dropped moderately in 1951. Approximately three-fourths of the output of silver from 1945 to 1951 was recovered as a byproduct of base-metal mining and gold mining. The current rate of silver production is far below the prewar average.

All tonnage figures used in this section are short tons of 2,000 pounds "dry weight"; that is, they do not include moisture. Figures in cubic yards used in measuring material treated in placer operations are "bank measure"; that is, the material is measured in the ground before excavation. The weight unit for gold and silver is the troy ounce (480 grains). The totals are calculated upon the basis of recovered or recoverable fine gold and silver shown by assays to be contained in ore, bullion, and other material produced.

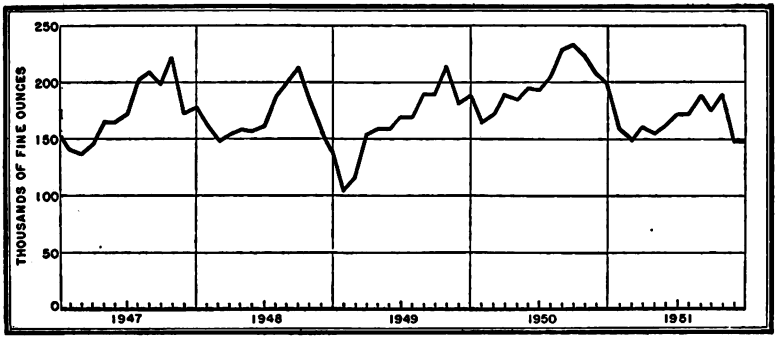

FIGURE 1.—Mine production of gold in the United States, 1947–51, by months, in terms of recoverable gold.

Mines are grouped in two main classes—placers and lodes. The placers are those in which gold and silver (and, in a few placers, platinum) are recovered from gravel as native metals or in natural alloy. Except for such small-scale hand methods as those utilizing the gold pan, the rocker, or the dry washer, all placer recovery methods employ sluice boxes; methods are distinguished by the means used for delivering the gravel to the sluices. Those methods where gravel is delivered mechanically include bucket-line dredging, dragline dredging, and treatment in nonfloating washing plants of gravel delivered by power shovel, dragline excavator, truck, slackline scraper, or other mechanical means. In the hydraulic method the gravel is mined from the bank by a powerful jet of water; in some small-scale hand methods the gravel is shoveled into sluices; and in drift operations the gravel is mined underground and delivered to sluices at the surface. The lode mines are those yielding gold and silver from ore (as distinguished from gravel), mainly from underground workings, and, in addition to those worked chiefly for one or both of the precious metals, include those that yield ore mined chiefly for copper, lead, zinc, or other metals but contribute the precious metals as byproducts. As far as possible, the mine unit used is not the operator but the mining claim or group of claims.

PRINCIPAL MINING DISTRICTS AND LEADING MINES

Lawrence County (Lead), S. Dak., which had been the leading gold producer for many years, was surpassed in 1943, 1944, and 1945 by the West Mountain (Bingham), Utah, copper district, as a consequence of restrictions imposed on straight gold mining by War Production Board Order L–208 during the war. However, Lawrence County regained the lead in 1946 and has held this position through 1951; the West Mountain district ranked second in this period. Third place was held by the Grass Valley-Nevada City gold ore district in California in 1949, 1950, and 1951.

The leading silver-producing districts for many years have included many distinguished more for base-metal output than for silver yield, and this condition prevailed again in 1951. The three leading districts produced about 62 percent of the total United States output of silver in 1951.

Of the 25 leading gold-producing mines, 9 were lode gold mines, 5 were placers (of which 4 were worked by bucket-line dredges and one by open-cut and treatment plant), 3 were copper mines, 4 were zinc-lead mines, and 1 was a zinc-copper mine; 3 produced over 1 type of ore. The 3 leading mines contributed 46 percent of the total gold produced in the United States in 1951, and the entire 25 supplied 77 percent.

TABLE 4.—Mine production of recoverable gold in the United States, 1942–46 (average) and 1947–51, by districts that produced 10,000 fine ounces or more during any year (1947–51), in fine ounces [1]

TABLE 6.—Twenty-five leading gold-producing mines in the United States in 1951, in order of output

Rank	Mine	District	State	Operator	Source of gold
1	Homestake	Whitewood	South Dakota	Homestake Mining Co	Gold ore.
2	Utah Copper	West Mountain (Bingham)	Utah	Kennecott Copper Corp	Copper ore.
3	Fairbanks Unit	Fairbanks	Alaska	U. S. Smelting, Refining & Mining Co	Dredge.
4	Natomas	American River (Folsom)	California	Natomas Co	Do.
5	Brunswick-Idaho-Maryland	Grass Valley-Nevada City	do	Idaho Maryland Mines Corp	Gold ore.
6	Yuba Unit	Yuba River	do	Yuba Consolidated Gold Fields	Dredge.
7	Nome Unit	Nome	Alaska	U. S. Smelting, Refining & Mining Co	Do.
8	Empire Star group	Grass Valley-Nevada City	California	Empire Star Mines, Ltd	Gold ore.
9	Ruth Pit	Robinson	Nevada	Kennecott Copper Corp	Copper ore.
10	New Cornelia	Ajo	Arizona	Phelps Dodge Corp	Do.
11	Gold King	Wenatchee River	Washington	Lovitt Mining Co	Gold ore.
12	Copper Queen	Warren (Bisbee)	Arizona	Phelps Dodge Corp	Copper, zinc-lead ores.
13	Holden Group	Chelan Lake	Washington	Howe Sound Co	Zinc-copper ore.
14	Iron King	Big Bug	Arizona	Shattuck Denn Mining Corp	Zinc-lead ore.
15	Yellow Pine	Yellow Pine	Idaho	Bradley Mining Co	Gold ore.
16	Knob Hill	Republic	Washington	Knob Hill Mines, Inc	Do.
17	Treasury Tunnel-Black Bear	Upper San Miguel	Colorado	Idarado Mining Co	Zinc-lead-copper ore.
18	Round Mountain	Round Mountain	Nevada	Round Mountain Gold Dredging Co	Placer.
19	Goldacres	Bullion	do	London Extension Mining Co	Gold ore.
20	Portland, Dakota, Clinton	Portland, Bald Mountain	South Dakota	Bald Mountain Mining Co	Do.
21	Resurrection Group	California	Colorado	Resurrection Mining Co	Zinc-lead ore.
22	Smuggler Union, etc	Upper San Miguel	do	Telluride Mines, Inc	Do.
23	United States and Lark	West Mountain (Bingham)	Utah	U. S. Smelting, Refining & Mining Co	Gold-silver, lead, silver, zinc-lead ores.
24	Park Galena and Mayflower	Park City	do	New Park Mining Co	Zinc-lead ore.
25	Old Eureka	Mother Lode	California	Central Eureka Mining Co	Gold ore.

[1] States east of the Mississippi figures are peaks since 1896, except New York and Pennsylvania, which are peaks since 1905. The Illinois figure is the peak since 1907. Alaska, California, Nevada, and Oregon are peaks since 1880. For earliest year of record for other States, see respective State chapters in this volume.

[2] Includes a small quantity for New Hampshire.

Only 5 of the 25 leading silver-producing mines depended exclusively on silver ore; ores valuable chiefly for copper, lead, zinc, and gold supplied most of the silver production. The nine leading mines each producing over 1,000,000 ounces of silver in 1951 contributed 57 percent of the United States total. The entire 25 mines supplied 76 percent of the United States output. As several operators worked more than one of the leading silver mines as well as some smaller mines, the output of silver by companies was substantially more concentrated than that by mines.

ORE PRODUCTION, CLASSIFICATION, METAL YIELD, AND METHODS OF RECOVERY

Tables 10 to 15 give details of classes of ore, metal yield in fine ounces of gold and silver to the ton, and gold and silver output by classes of ore and by methods of recovery, embracing all ores that yielded gold and silver in the United States in 1951. These tables were compiled from the individual State chapters in this volume, in which more detailed data are presented.

The classification originally adopted in 1905 on the basis of smelter terminology, smelter settlement contracts, and metal recovery has been used continuously in succeeding years, except for modifications necessitated by the improvement in metallurgy and the lowering of the grade of complex ores treated. The copper ores include those smelting ores that contain 2.5 percent dry assay or more of copper

[1] Missouri excluded.
[2] Includes copper precipitates and old slag.
[3] Includes old slag and tungsten ore.
[4] Includes 5,892 tons of ore and contained recoverable metal from the former Metals Reserve Company stockpile at Jean, Nev.
[5] Excludes magnetite-pyrite-chalcopyrite ore and gold and silver therefrom.

Digitized by Google

(or less than this percentage if no other metal is present); or those ores concentrated chiefly for their copper content. The lead ores are those that contain 5 percent dry assay or more of lead (minimum lead-smelting charge requires 7.5 to 8.5 percent wet assay), irrespective of precious-metal content, and ores that carry any grade of lead exclusively. Zinc smelting ores (chiefly oxides) had ranged from 16 to 45 percent zinc; but, with the development of slag fuming, which permits some oxidized ore in the charge, and with high zinc prices, the minimum has declined to as low as 5 percent recoverable zinc. Zinc concentrating ores include any grade of zinc ore that makes marketable zinc concentrate, irrespective of precious-metal content. The mixed ores are combinations of those enumerated.

Gold, gold-silver, and silver ores containing too little copper, lead, or zinc to be classified as copper, lead, zinc, or mixed base-metal ores are called "dry" ores, regardless of the ratio of concentration, except low-grade ore milled chiefly for its copper content and having very little or no precious-metal content (chiefly the "porphyry coppers") and ores from which separate products of lead concentrates and zinc concentrates are made. The crude ore into the mill in these two exceptional instances thus takes its name from its products—a name that is also justified by the mineralogical content and final recovery of metals. The "dry ores" thus are ores, chiefly siliceous, valuable for their gold and silver content and, in some instances, their fluxing properties, regardless of method of treatment. Dry gold ores are those that by inspection are overwhelmingly of gold content; a similar qualification applies to silver ores; decision as to "gold-silver" ore is made on a basis of value, using the rule that the bimetal classification is not used unless the metal of lower value equals or exceeds one-quarter of the combined value of the gold and silver.

The lead, zinc, and zinc-lead ores in most districts in the States east of the Rocky Mountains carry no appreciable quantity of gold or silver; such ores are excluded from this report unless otherwise indicated.

[1] Less than 0.01 percent.

PLACERS

Approximately 25 percent of the gold produced in 1951 was derived from placer mines. Of the 490,525 ounces of placer gold, 404,305 ounces (82 percent) was recovered by bucket-line dredges. This dredge output was nearly fourfold greater than that of 1944, the wartime low, but was far below the alltime high of 904,149 ounces established in 1940.

The quantity of gold recovered by bucket-line dredges from the inception of the industry as a commercial factor in 1896 to the end of 1951 is recorded as 22,223,306 ounces, originating by States as follows: California, 13,186,045 ounces; Alaska, 6,293,660 (including the production from single-dipper dredges and some gold by hydraulicking); Montana, 785,419; Idaho, 694,841; and other States, 1,263,341.

Digitized by Google

The second most important source of placer gold was nonfloating washing plants, with mechanical earth-moving equipment for gravel delivery. Production by this method has been generally upward since 1944. Production by dragline dredging dropped sharply but remained in third place in 1951. Production by hydraulicking regained fourth place in 1951 over production by small-scale hand methods.

[1] Includes Alaska.
[2] A mine using more than 1 method of recovery is counted but once in arriving at total for all methods.

Digitized by Google

Alaska produced 49 percent of the United States placer gold in 1951, California 38, and Nevada 6. Other important producers, in order of output, were Colorado, Idaho, Oregon, and Montana. Alaska led in production by bucket-line dredging, nonfloating washing plants, hydraulicking, and underground placer mining and California by dragline dredging, suction dredging, and small-scale hand methods.

Table 16 shows the placer gold produced in the United States, classified by mining methods, in 1947–51.

Additional information on placer mining may be found in the State reviews of this volume.

REFINERY PRODUCTION

Table 17 contains official estimates of production of gold and silver in the United States, made by the Bureau of the Mint, based upon arrivals at United States mints and assay offices and at privately owned refineries. The mints and assay offices determine the State source of all newly mined unrefined material when deposits are received. The State source of material received by privately owned refineries is determined from information submitted by them and by intervening smelters, mills, etc., involved in the reduction processes.

TABLE 17.—Gold and silver refined in the United States, 1947–51, and approximate distribution by source (State), in 1951, in fine ounces

[U. S. Bureau of the Mint]

State or Territory	Gold	Silver
1947	2,165,318	38,587,069

CONSUMPTION AND USES IN INDUSTRY AND THE ARTS

Monetary use has claimed by far the largest part of the gold and silver output through the years, but this use to a large extent takes the form of stockpiling in Government and private hoards that can be made available to industry and the arts without smelter or refinery preparation. In contrast, the gold and silver that enter industry and

Digitized by Google

the arts are consumed much as are other metals, any return as secondary metal requiring the usual channels of collection, smelting, and refining. The consumption of gold and silver in the arts antedates written history, but industrial use of these two metals is a comparatively recent development.

TABLE 18.—Gold and silver produced in the United States, 1792–1951 [1]

Period	Gold		Silver	
	Fine ounces	Value [2]	Fine ounces	Value [3]
1792–1847	1,187,170	$24,537,000	309,500	$404,500
1848–73	60,021,278	1,240,750,000	146,218,600	193,631,500
1874–1951	225,062,723	5,474,735,080	3,960,565,930	2,989,995,398

[1] Includes Alaska. From Report of the Director of the Mint. The estimates for 1792–1873 are by R. W. Raymond, Commissioner of Mining Statistics, Treasury Department, and since then, by the Director of the Mint.
[2] Gold valued in 1934 and thereafter at $35 per fine ounce.
[3] Silver valued in 1934 and thereafter at Government's average buying price for domestic product.

Gold.—The arts require a much larger quantity of gold than does industry, but the metal's corrosion resistance and other properties have resulted in some industrial demand. Consumption in the arts increased rapidly during the war. A high marriage rate and widespread prosperity have increased the sale of jewelry, watches, and many luxury items made of gold. Comparison of 1951 gold figures with those for 1950 shows an 3-percent decrease in the return from industrial use, a 22-percent decrease in issue for industrial use, and a 29-percent decrease in net consumption. The net absorption by industry and the arts exceeded the total new gold produced from domestic mines during 1951 slightly.

TABLE 19.—Net industrial [1] consumption of gold and silver in the United States 1942–46 (average) and 1947–51

[U. S. Bureau of the Mint]

Year	Gold (dollars)			Silver (fine ounces)		
	Issued for industrial use	Returned from industrial use	Net industrial consumption	Issued for industrial use	Returned from industrial use	Net industrial consumption
1942–46 (average)	127,041,429	28,327,873	98,713,556	155,625,825	45,066,086	110,559,739

1951	105,012,094	35,535,115	69,476,979	151,650,905	46,650,905	105,000,000

[1] Including the arts.

Silver.—The 1951 net consumption of silver in the arts and industry continued at a high level, although it declined about 5 percent below that of 1950.

Widespread prosperity and a high marriage rate sustained postwar demand for sterling and plated silverware, jewelry, watchcases, church articles, pens, pencils, and other items largely in the luxury

Digitized by Google

class. Consumption was large in photography, particularly for motion pictures. The industrial uses of silver had grown greatly during the war and continued to absorb much silver thereafter, although on a reduced scale.

MONETARY STOCKS

Gold holdings of the United States declined $11 million from $22,706 million on December 31, 1950, to $22,695 million on December 31, 1951, according to the Federal Reserve Bulletin. The low for 1951 was reached in June, when reserves had declined to $21,756 million, corresponding to a decrease of $950 million from January; however, the outflow of gold from the United States reversed itself sharply in July, with the result that the net decline in 1951 was slight. Total world reserves are not positively known, inasmuch as data are not available for some countries, including Germany, Japan, Australia, and the Soviet Union. However, the Federal Reserve Board estimates that world monetary reserves of gold on December 31, 1951, totaled $35,950 million, exclusive of holdings of the Soviet Union.

During the war the United States reserves of gold decreased by more than $2,500 million, but the flow of gold reversed in 1946, and the country's reserves rose steadily in the 3 years following, with a net gain of about $4,400 million, to set a new record high in the latter part of 1949. Largely as a consequence of credits extended under the Marshall Plan, gold moved regularly from the United States during nearly 2 years following September 1949 until the end of June 1951, with an overall decline in reserves in this period of about $2,800 million.

Silver holdings of the United States Treasury decreased 18 million fine ounces during 1951 to 1,965 million ounces. The holdings do not include 410,553,011 ounces released under lend-lease agreements that provide for the return of this silver.

Demand by governments for silver for coinage rose from 42 million ounces in 1950 to approximately 89 million ounces in 1951. Of this quantity, the United States consumed 44,440,000 ounces, Saudi Arabia 26,000,000, Western Germany 9,900,000, Mexico 4,500,000, and Canada 3,800,000.

PRICES

Since January 1934 the price of gold at the United States Mint has been $35 per fine troy ounce. The Treasury buying price for silver domestically mined after July 1, 1939, was fixed at $0.711+ per ounce on July 6, 1939; on July 31, 1946, the President approved an act (Public Law 579, 79th Cong.) which provided that the seigniorage to be deducted for silver mined after July 1, 1946, and delivered to the Treasury be reduced from 45 percent to 30 percent. The effect was to raise the price of domestically mined silver to 90.50505 cents an ounce; there has been no price change since.

The average price of pound-sterling exchange in New York (buying rates for cable transfers, as certified by the Federal Reserve Bank of New York) was: January 1948–August 1949, $4.03; September 1949, $3.44; and October 1949–December 1951, $2.80). The London price of silver, per ounce, 0.999 fine, as reported by the Director of

Digitized by Google

the Mint, opened in 1948 at 45d., a level maintained past midyear, when after a short upward movement it fell to 42.5d. by the year end. Changes in 1949 were of little significance until devaluation of the pound in September, following which the price rose to 64d., where it remained the rest of the year. Prices in 1951 ranged from a low of 70d. to a high of 78½d. (equivalent, in United States currency, to $0.81687 and $0.91606). The New York price, per ounce, 0.999 fine, opened in 1951 at $0.8000 but rose to $0.9016 early in January, based on actual transactions at $0.9041 (the approximate equivalent of the Treasury buying price of $0.9050+ per fine ounce for domestic production). This price resulted from the necessity of selling some Treasury silver to satisfy trade requirements. The price declined to $0.8775 early in June but soon returned to the $0.9016 level. Early in October it broke sharply to $0.8475 but quickly rose to $0.8800 and remained at this price to the end of the year.

FOREIGN TRADE [1]

The excess of gold imports over exports that prevailed from 1946 through 1949 was replaced in 1950 by an excess of exports over imports, and this situation continued through June 1951, after which imports again began to exceed exports. Excess exports of gold plus consumption in the arts and industries exceeded the domestic production. As has been normal for many years, imports of silver exceeded exports by a wide margin.

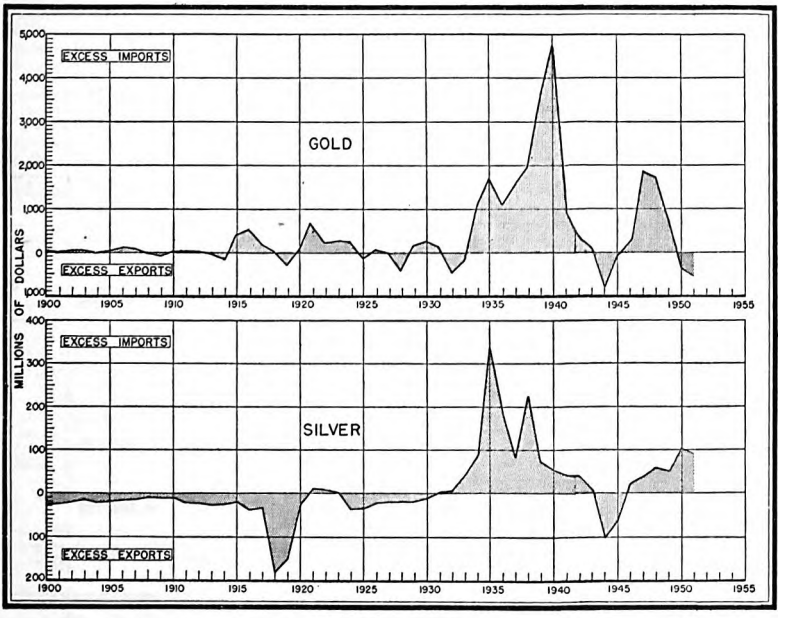

FIGURE 3.—Net imports or exports of gold and silver, 1900–51.

[1] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

TECHNOLOGY

During 1949 and 1950 studies were made at the Rare and Precious Metals Experiment Station of the Bureau of Mines, Reno, Nev., to determine simple treatment methods employing the least possible equipment to produce satisfactory results on marginal ores and in small-scale operations. Tests were made on oxide ores and on sulfide ores that contain gold and silver and in some instances base metals. The methods of treatment investigated included gravity concentration, amalgamation, flotation, and cyanidation. No attempts were made during these studies to develop new methods for low-grade or refractory ores if simple treatment was not satisfactory.[2]

Research was continued along two lines: First, investigation of repeated reuse of activated carbon in the carbon-cyanidation process, which permits a simplified treatment of ore pulps that are difficult to settle or from which it is difficult to produce clarified pregnant solution. This process eliminates considerable plant equipment, and gold is recovered in an easily handled form.

The second line of research was the continued investigation of possible improvement of the cyanide process in regard to accelerating the solution of gold and silver, the increase of recovery, or both. A large number of addition reagents were tested, including many new organic materials. Some slight improvements were obtained, but the investigation was being continued in the hope of important achievements.

WORLD REVIEW

World output of gold rose slightly in 1951, continuing the movement that has prevailed since 1946, but the 1951 total was well below the annual quantities produced before World War II. World silver output was the same in 1951 as in 1950. Substantial declines in the United States and Mexico were offset by increases in Canada, Peru, West Germany, and South-West Africa and other countries.

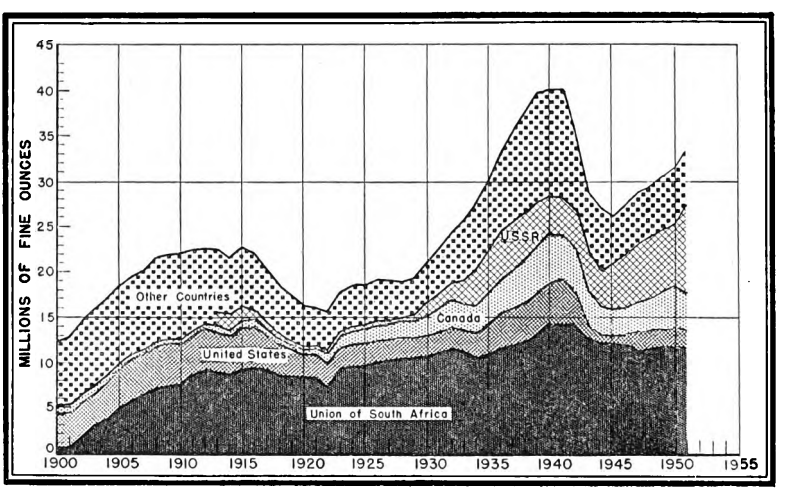

FIGURE 4.—World production of gold, 1900–51.

[1] Figures used derived in part from American Bureau of Metal Statistics. For some countries accurate figures are not possible to obtain owing to clandestine trade in gold. Data not available for Austria, Bulgaria, Germany, Thailand, and Yugoslavia; estimates included in the total. In addition, production in Cyprus, and Indochina was negligible.
[3] Refinery production. Excludes production of the Philippines.
[3] Revised figure.
[4] Imports into United States.
[5] Exports.
[6] Estimate.
[7] Data not available; estimate included in total.
[8] Output from U. S. S. R. in Asia included with U. S. S. R. in Europe.
[9] Includes Ruanda-Urundi.
[10] Included is yield from Nkana mine refinery slimes accumulated during the war: 547 ounces in 1947, 999 in 1948, 972 in 1949, and 1,296 in 1950.

TABLE 26.—World production of silver, 1947–51, by countries in fine ounces [1]—Continued

Country [1]	1947	1948	1949	1950	1951
Oceania:					
Australia:					
Commonwealth	9,527,140	10,057,519	9,849,213	10,677,456	10,436,324
New Guinea [9]	35,421	31,739	31,786	30,399	(4)
Fiji	33,237	29,187	29,755	37,736	24,869
New Zealand	221,984	232,563	232,599	199,701	133,291
Total	9,818,000	10,351,000	10,143,000	10,945,000	10,625,000
World total (estimate)	167,700,000	[2] 173,200,000	[2] 173,800,000	[2] 198,600,000	198,600,000

[1] Silver is also produced in Bulgaria, Cyprus, Hong Kong, Hungary, Malaya, Indonesia, Poland, Sarawak, Sierra Leone, Turkey, and U. S. S. R.; production data are not available, but estimates are included in total.
[2] Revised figure.
[3] Imports into the United States. Scrap is included in this figure in many instances, most notably in the case of Cuba.
[4] Data not available; estimate included in total.
[5] Exports.
[6] Estimate.
[7] American and British zones only.
[8] Recovered from an accumulation of refinery slimes.
[9] Fiscal year ended May 31 of year following that stated.

Australia.—Gold production in Australia in 1951 was 886,170 ounces, a 2-percent increase over that of the preceding year. The reaction of Australia to the announcement of September 1951 of the International Monetary Fund on gold disposal was to permit the entire current Australian output of gold to be sold in the "free market," provided such sales were made with payment in United States dollars. Silver production in Australia declined from 10,677,456 ounces in 1950 to 10,436,324 in 1951.

Canada.—Although gold production dropped 3 percent from 1950 to 4,328,931 ounces, gold once again was the leading mineral in Canada in output value in 1951. Ranking third among the gold-producing countries of the world, Canada was exceeded in output by only South Africa and (probably) the U. S. S. R. A feature of the gold-mining industry in Canada in 1951 was the decision of the Canadian Government to allow, with some restrictions, sale of the current production of gold in the "free market." Properties receiving subsidy (most of the straight gold mines) under the Emergency Gold Mining Assistance Act forfeited rights to such aid if they elected to dispose of their output on the open market. However, several companies chose this course and were reported to have sold considerable gold at $39.30 to $39.55 per ounce, apparently for export to the European market.

The gold outputs of the provinces or territories in 1950 and 1951 were as follows, in fine troy ounces:

Province or Territory:	*1950*	*1951*
Alberta	152	97
British Columbia	290,490	252,015
Manitoba	191,725	162,257
Newfoundland	9,254	8,070
Northwest Territories	200,663	210,451
Nova Scotia	65	17
Ontario	2,481,110	2,445,902
Quebec	1,094,645	1,061,113
Saskatchewan	79,784	113,967
Yukon	93,339	75,042
Total	4,441,227	4,328,931

Digitized by Google

Of the 1951 output of gold, 84 percent was obtained by straight gold-lode mining, 13 percent as a byproduct of base-metal mining, and 3 percent by placer-gold mining.

Continuing an uptrend that started in 1948, silver production in Canada in 1951 rose 4 percent to 24,244,949 ounces; a large portion of the output was byproduct silver from base-metal ores. Canada ranked third in silver production in the world, exceeded by Mexico and the United States.

Colombia.—Gold production in Colombia in 1951 was 430,723 ounces, equivalent to a 14-percent increase above the 1950 figure. The gold production thus continued an uptrend that began in 1949 after a steady decline that started in 1941. About three-fourths of the 1951 output was obtained from placer mining and one-fourth from gold-lode mines. The silver production increased 12 percent to 130,028 ounces. The entire silver yield of Colombia was recovered as a byproduct of gold mining.

Honduras.—Honduras was the leading silver producer of the Central American countries and ranked sixth among the countries of the Western Hemisphere. The principal mines were the San Juancito and El Mochito of the New York & Honduras Rosario Mining Co. According to Mineral Trade Notes[3] the San Juancito produced 2,145,602 ounces of silver and 15,283 ounces of gold in 1951, and El Mochito 1,027,602 ounces of silver and 700 ounces of gold. Smaller producers also contributed some gold and silver. The Compania Minera Agua Fria ceased mining and milling operations on October 31, 1951. Honduras exported 3,309,680 ounces of silver and 33,578 ounces of gold in 1951.

Mexico.—Although silver production in 1951 dropped sharply to 43,797,734 ounces, Mexico maintained its position as the leading silver-producing country of the world. Gold production declined 3 percent from 1950 to 394,007 ounces.

Silver exports were high, but mostly in the form of currency minted in Mexico. Shipments were made to Saudi Arabia, West Germany, and Italy.

Republic of the Philippines.—Gold mining in the Philippines continued to recover from the dislocations caused by World War II, and gold production rose 18 percent over 1950 to 393,602 ounces in 1951. The alltime high of the Philippines was 1,144,332 ounces in 1941, produced by some 54 properties. Eleven mines were in active production in 1951 compared with 9 in 1950; rehabilitation from damage suffered during the war was almost completed in 2 additional properties. Gold producers in the Philippines were benefited by regulations that permitted them to sell up to 75 percent of their respective outputs in the domestic "free market," where it was reported the prevailing prices averaged well over $50 per ounce during 1951.[4]

Union of South Africa.—Both the quantity of ore milled and the quantity of gold produced in the Union of South Africa in 1951 were approximately 1 percent below those of the preceding year; the average yield of gold per ton of ore was slightly less. The average working cost per ton of ore was up 7 percent, but the overall average

revenue per ton was sustained by sale of some of the output of gold at premium prices on the free market.

Progress was made in the development of the new gold field in the Orange Free State about 150 miles south-southwest of Johannesburg. Investigations since 1937 have shown that gold-bearing conglomerate beds or "reefs," generally similar to those mined in the Rand, underlie an area about 30 miles long and 10 miles wide; it was estimated that the new field had a production potential of 8 million ounces of gold annually. The field was divided into 13 separate holdings, on which 25 shafts had been or were being sunk. Two properties reached the production stage in 1951, and 4 more were expected to go into production in 1952.

TABLE 27.—Salient statistics of gold mining in the Union of South Africa, 1947–51

[Transvaal Chamber of Mines]

	1947	1948	1949	1950	1951

Graphite

By Frank D. Lamb and E. V. Blankenbaker

GENERAL SUMMARY

EARLY in 1951 there was a critical shortage of flake graphite in the United States, caused by an increase in world demand for Madagascar graphite, Government purchasing, and lack of consumer stocks, depleted during previous years when the supply was short. During the year consumers could obtain enough graphite for current needs, as production in Madagascar reached an alltime high, increasing from 14,013 metric tons in 1950 to 18,340 in 1951.

Production of domestic natural graphite in 1951 increased 40 percent over 1950. The total value of domestic graphite shipments in 1951 increased 80 percent over 1950 to $771,434, partly as a result of a 21-percent increase in the quantity shipped but mainly because of a 48-percent increase in the average unit value of shipments in 1951 compared with 1950. Domestic graphite mines were still in an unfavorable position with respect to long-range competition from foreign sources because of their lower grade, higher costs, and the preference of consumers for foreign material. However, domestic producers had little difficulty in selling their limited current production.

The prices paid to foreign sources by consumers in the United States increased steadily during the year, and the ceiling prices established by the Government in July resulted in narrowing the margin between cost of production and selling price for processors. However, in August the Government exempted crude natural graphite and graphite concentrates from price controls and in December removed controls from foundry facings. Minimum quantity figures on consumption of natural graphite increased 83.5 percent over 1950.

TABLE 1.—Salient statistics of the graphite industry in the United States, 1950–51

	1950		1951	
	Short tons	Value	Short tons	Value
Natural graphite:				
Production	5,102	(1)	7,135	(1)
Sales	5,605	$427,908	6,808	$771,434
Consumption [2]	20,878	3,010,761	38,318	5,083,527
Imports:

PRODUCTION AND SALES

Production and sales of domestic natural graphite in 1951 were substantially greater than in 1950. The combined total of crystalline and amorphous graphite produced from domestic mines in 1951 was 7,135 short tons compared to 5,102 tons in 1950. Shipments were 6,808 short tons valued at $771,434 compared with 5,605 tons valued at $427,908 in 1950. The manufacture of artificial graphite was continued at Niagara Falls, N. Y., by the Acheson Graphite Division of the National Carbon Co., Inc., 30 East 42d St., New York 17, N. Y. Statistics on production and consumption of artificial graphite are collected by the Bureau of Mines, but the figures cannot be disclosed because there is only one producer.

There were three domestic producers of natural graphite in the United States in 1951, in Alabama, Texas, and Rhode Island. The small number of producers does not permit publication of separate statistics on natural crystalline and amorphous graphite However, table 2 shows combined figures for 1946 through 1951.

TABLE 2.—Production and shipments of natural graphite in the United States, 1946-51

Year	Production (short tons)	Shipments		Year	Production (short tons)	Shipments	
		Short tons	Value			Short tons	Value
1946	5,575	4,844	$252,596	1949	6,102	5,213	$475,264
1947	4,387	5,207	221,260	1950	5,102	5,605	427,908
1948	9,949	9,871	450,759	1951	7,135	6,808	771,434

CONSUMPTION

In 1950 and early in 1951 there was a shortage of flake graphite in the United States, and consumers experienced great difficulty in obtaining crucible-grade graphite from Madagascar. However, during 1951 production in Madagascar increased, enabling consumers to obtain enough graphite for all their current needs.

Although coverage of the graphite-consumption canvass is incomplete, the totals obtained indicate at least the minimum quantities of graphite used in making various products. Domestic consumption of natural graphite reported for 1951 is shown in table 3.

Batteries	3,189	173,121	Bearings	84	39,739
Pencils	2,276	572,934	Other [2]	4,469	758,740
Stoppers, sleeves, and nozzles	1,466	296,147	Total	38,318	5,083,527

[1] Minimum quantities; coverage incomplete.
[2] Includes brake lining, carbon brushes, electrodes, etc.

PRICES

Quotations for graphite continued to increase during 1951 on certain grades, and at the year end the trade-journal listings were as follows: Per pound, carlots, f. o. b. shipping point: Crystalline flake, natural; 85–88 percent carbon, crucible grade, 13 cents; 96 percent carbon, special and dry usage, 22 cents; 94 percent carbon, normal and wire drawing, 19 cents; 98 percent carbon, special for brushes, etc., 26½ cents.

Amorphous, natural, for foundry facings, etc., up to 85 percent carbon, 10 cents.

Madagascar, c. i. f. New York, "standard grades, 85–87 percent carbon," $250 per short ton; special mesh $300–$325; special grade, 99 percent carbon, $725.

Amorphous graphite, Mexican, f. o. b. point of shipment (Mexico), per metric ton, $9–$16, depending on grade.

As the prices paid to foreign sources by consumers increased, the ceiling prices established by the Government on July 26, 1951, resulted in a narrowing of the margin between cost of production and selling price for consumers. However, on August 10, 1951, the Government exempted natural graphite, either as crude ore or concentrates, from price controls and in December removed foundry facings from price controls.

FOREIGN TRADE [1]

Imports of crystalline flake graphite increased sharply in 1951. Imports of this type of graphite amounted to 10,227 short tons valued at $1,412,787—an increase of 67 percent in quantity and 95 percent in value from the 1950 figures. Natural amorphous graphite imports also increased in 1951 over 1950, resulting in a substantial increase in the total imports of all types of graphite as shown in table 4.

[1] Less than 0.5 ton.

The United States tariff rates on graphite, effective January 1, 1948, were still in force during 1951. They were: Amorphous, natural and artificial, 5 percent ad valorem; crystalline flake, 15 percent ad valorem, with a specific minimum of 0.4125 cent per pound and a specific maximum of 0.825 cent per pound; crucible flake and dust and other crystalline lump and chip, 7½ percent ad valorem.

Exports of natural graphite, 1947–51, were: 1947, 1,546 tons, $171,607; 1948, 1,047 tons, $127,931; 1949, 1,352 tons, $158,694; 1950, 1,397 tons, $173,700; 1951, 1,504 tons, $195,948.

[4] Estimated Japanese imports from Manchuria.
[5] Estimate.
[6] Republic of Korea only.

After reaching a production of 15,311 metric tons in 1940, output of graphite in Madagascar slumped during and after World War II. In 1950 production reached 14,013 metric tons and rose to a record 18,340 metric tons in 1951. This unprecedented increase in output made it possible to meet the requirements of industry, both in the United States and other countries, and also to make substantial shipments on United States Government contracts, which had fallen far in arrears. The increased production was attributed to modernization by mining companies, which received equipment from the United States, and to higher prices received for graphite.

Exports of graphite from Ceylon were 12,824 metric tons in 1951, of which the United States received 5,240 metric tons or approximately 41 percent. This was not adequate to take care of all the needs of industry in the United States and fulfill the requirements of the United States Government. Especially difficult to obtain were the higher grades of Ceylon amorphous lump graphite containing 97 percent carbon or better.

Mexican amorphous graphite was in good supply, although railroad-car shortages, labor difficulties, and lack of priority ratings to obtain operating supplies were said to have hindered industry efforts to maintain steady receipts of this supply.

Gypsum

By Oliver S. North and Nan C. Jensen

GENERAL SUMMARY

THE YEAR 1951 again witnessed high production of gypsum and gypsum products and the setting of some new industry records. A greater available productive capacity than in past years, along with other favorable factors, enabled the industry to meet the demand for its many products with a minimum of delay.

Although new nonfarm housing starts were about 300,000 fewer in 1951 than 1950, public construction and private industrial building were both higher. This condition, combined with a backlog of requirements for many housing units started in 1950 but uncompleted at the end of that year, resulted in the maintenance of sales of gypsum building products at approximately the 1950 levels.

Although the quantity of crude gypsum mined in the United States and the tonnage of crude imported both increased in 1951 over 1950, most use-classification gains were made by the major uncalcined products—agricultural gypsum and portland-cement retarder. The quantity of calcined gypsum produced was slightly higher in 1951; the quantity used in wallboard and laminated board more than accounted for the entire increase. The tonnages of calcined gypsum used in both plasters and lath declined.

At the end of 1951 the immediate outlook for the gypsum industry was somewhat uncertain. Although it appeared likely that the peak of home building had been passed, public and industrial construction promised to continue at a high rate in 1952. The backlog of orders for most gypsum building products had been largely filled, and at least a temporary tapering off in the output of those materials was in prospect. On the other hand, there seemed no reason that the sales of both cement retarder and agricultural gypsum should not at least reach their 1951 volumes.

DOMESTIC PRODUCTION

Crude.—The output of crude gypsum from mines in the United States reached a record high of 8,665,500 short tons in 1951—a 6-percent increase over the 1950 figure, which was the previous record. Increased quantities were mined in California, Iowa, Michigan, Nevada, Texas, and the Arizona-Arkansas-Kansas-Louisiana-New Mexico group, compared with 1950. A total of 55 mines reported

[1] Production of some States is not shown separately, in order not to disclose individual company operations.

output in 1951; of these, 39 were open-pit operations, 13 were underground mines, and 3 were combination pit-underground mines.

Calcined.—Fifty plants, with 225 pieces of calcining equipment, produced 7,454,900 short tons of calcined gypsum in 1951. This output established a new record, 2 percent above the previous record year, 1950. Production of calcined gypsum, the form in which most gypsum is utilized, is considered the most accurate overall yardstick of the industry, as it includes both domestic and imported raw material.

[1] Includes rotary and beehive kilns, grinding-calcining units, and hydrocal cylinders.
[2] Comprises calcining plants in 1949–51 as follows: 1 each in Arizona (none in 1951), Connecticut, Florida, Georgia, Indiana, Maryland, Massachusetts, New Hampshire, New Jersey, New Mexico (none in 1950–51), Oklahoma, and Pennsylvania; 2 each in Colorado, Kansas, Montana, Nevada, Ohio, and Virginia; 3 in Utah.

Mine and Calcining-Plant Developments.—National Gypsum Co., Buffalo, N. Y., announced plans for a major expansion of its Medicine Lodge, Kans., plant. Two calcining kettles were to be added to the present facilities, and new and improved equipment at the mine was expected to double the output of crude rock. The present plant, formerly owned by Best Bros., has been in operation for half a century. It produces Keene's cement, dental plaster, plaster of Paris, paper filler, etc.[1]

Northwest Gypsum Co. was reported in midsummer to have officially placed in operation its open-pit mine near Weiser, Idaho, and its mill at Huntington, Oreg., which was said to have a rated capacity of 500 tons of crushed material per day. Initial production of gypsum fertilizer was planned, with production of cement retarder and other products to begin later.[2] However, the company produced only a small, experimental quantity of agricultural gypsum by the end of 1951.

Certain-teed Products Corp. purchased the plant facilities and about 500 acres of gypsum deposits from Union Gypsum Co., Phoenix, Ariz. The acquisition increased to seven the number of Certain-teed Products Corp. plants now in operation.[3]

Columbia Gypsum Products, Inc., Velox, Wash., was reported to be producing agricultural gypsum, using crude rock from deposits near Windermere, British Columbia, Canada. The company planned construction of a calcining plant, to have a daily capacity of 10 tons of hardwall plaster.[4]

Laucks Chemical Co., Seattle, Wash., reported plans to increase the output of its Okanogan County, Wash., gypsum mine to between 4,500 and 5,000 tons in 1951.[5]

CONSUMPTION AND USES

Total expenditures in the United States for new construction amounted to $29.9 billion in 1951 compared with $27.9 billion in 1950. This increase reflected higher average construction costs, since the estimated physical volume of work accomplished was down slightly from 1950 record levels. A total of about 1,090,000 new nonfarm dwelling units were placed under construction in 1951. This was the second-best home-building year in history, although it was some 300,000 units below the 1950 figure.

Consumption of gypsum building products increased in 1951, even though housing starts declined, principally because the market was bolstered by a carryover demand from unfinished 1950 building units. Increased public construction and private industrial building also helped maintain demand for gypsum products at a high level. The gypsum industry, with greater available capacity than at any time in the past, apparently encountered no serious difficulties in meeting the continued high demand for its various products.

The total building uses of gypsum products, in dollar value, were 15 percent above 1950 and 50 percent above 1949.

Gypsum-Products Plant Developments.—Kaiser Gypsum, a division of Henry J. Kaiser Co., Oakland, Calif., acquired property near Seattle, Wash., on which it planned to build a gypsum calcining and

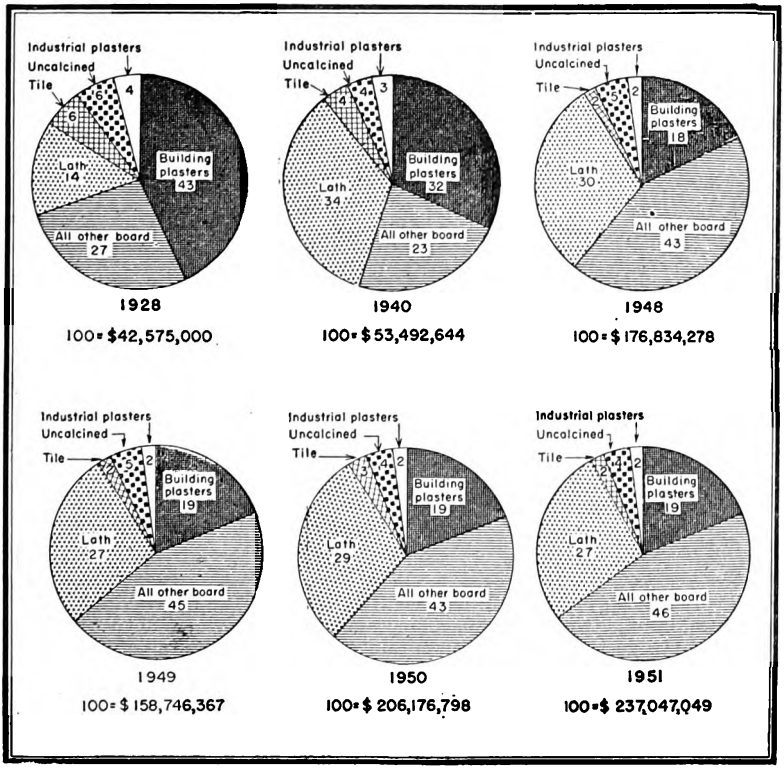

FIGURE 2.—Percentage distribution of total sales value, f. o. b. plant, of gypsum products in 1928, 1940, and 1948–51, by groups of products.

Digitized by Google

products plant. The project called for construction of the facilities needed to manufacture 100 million square feet of board annually, in addition to lath, sheathing, plaster, agricultural gypsum, and cement retarder. Raw gypsum would be obtained from deposits on San Marcos Island, off Lower California, Mexico. Kaiser Gypsum also operated gypsum plants at Long Beach and Redwood City, Calif.[6]

The expansion of National Gypsum Co. facilities at Medicine Lodge, Kans., included construction of a board plant over 800 feet long, to have a monthly capacity of 6 to 8 million square feet of lath and wallboard.[7] This action was a part of the company's broad expansion and improvement plans, which also included improvements and additions to its Fort Dodge, Iowa, operation, and building of a paper mill at Pryor, Okla.[8] However, work on the paper mill, which was to have been located on the site of the old Oklahoma Ordnance Works, was halted because the tense international situation created the possibility of reactivation of the ordnance works.[9] The company was later reported to be negotiating for the purchase of a different tract near Pryor on which to build the mill.[10]

Certain-teed Products Corp., Ardmore, Pa., reported plans for constructing a paper mill at Pryor, Okla., to manufacture paper for use at the company gypsum-board plants. The new mill would be operated by the Coronado Manufacturing Co., wholly owned sub-

sidiary.[11] An article described in detail the mining, calcining, and wallboard-manufacturing operations at the Fort Dodge, Iowa, plant of Certain-teed Products Corp.[12]

American Gypsum Co. announced plans for erecting facilities to produce Keene's cement and gypsum board at its plant near Green River, Utah. The crude gypsum would be mined from a deposit 10 miles west of Green River.[13]

[7] Figure withheld to avoid disclosure of individual company operations.

PRICES

According to reports from producers, the average value of crude gypsum mined was $2.77 per short ton, compared with $2.78 in 1950 and $2.77 in 1949. Among uncalcined uses, the unit value of cement retarder increased from $3.23 to $3.48 per ton, while that of agricultural gypsum declined from $4.28 to $3.99. The average values of the industrial plasters showed gains of approximately $2 per ton each. The value of miscellaneous cementitious plaster declined, while Keene's cement and all other building plasters, especially ready-sanded plaster, increased in average value. All of the prefabricated gypsum products increased in average value.

FOREIGN TRADE [14]

Imports of crude gypsum into the United States increased to 3,448,077 short tons, 90 percent of which was imported from Canada and represented about one-fourth of the total apparent domestic supply. Marked tonnage increases were noted from Jamaica and Mexico. Imports from the latter country have more than doubled in the last 3 years. A small tonnage of crude gypsum was shipped from the Dominican Republic into the United States.

[14] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

TECHNOLOGY

English scientists made a thorough study of the dehydration of gypsum and reported results in a series of four articles, as follows: I, A Study of the Thermal Decomposition of Gypsum by the Absorption of Oxygen and Nitrogen at 183°; II, A Study of the Thermal Dehydration of Gypsum by Means of Adsorption of Carbon Tetrachloride Vapor at 25°; III, Dehydration and Rehydration of Gypsum by Adsorption Methods; and IV, Heat of Immersion, Heat of Hydration, Specific Gravity, Sedimentation Volume, and Bulk Density of the Dehydration Products.[15]

A sulfate solubility test for dehydrated gypsum in portland cement was described. The test involves preparation of an aqueous extract of the cement, determination of the SO_3, Na_2O, and K_2O, and, as later modified, the CaO concentrations, and comparison of these values with the curve of Hansen and Pressler.[16]

The feasibility of producing ammonium sulfate commercially from gypsum and ammonium carbonate has attracted interest, both in the United States and abroad. A summary of plant developments and a brief description of the process now in use appeared in a trade press article.[17]

A recently issued patent described a new process by which sulfuric acid and cement can be produced from gypsum. Phosphate rock may be added for conversion into a superphosphate by the acid formed. The cement obtained is claimed to be of good quality and in sufficient quantity to offset the cost of the acid.[18]

WORLD REVIEW

Canada.—A booklet issued recently by the Canadian Department of Technical Surveys, Mines Branch, Ottawa, describes investigations into the beneficiation of Canadian gypsum. The booklet is designated as Memorandum Series 111, November 1950. The publication deals with a number of tests on low-grade gypsum, which constitutes the greater part of the raw material now available from economically workable deposits in central and western areas. Economic considerations have prevented development of gypsum deposits in many sections of Canada.[19]

The occurrences and geology of the gypsum deposits of southwestern Newfoundland were described at considerable length in an article. Reserves of gypsum and gypsum-anhydrite in this area are large.[20]

Cyprus.—In 1950, Cyprus' exports of gypsum reached record levels, with 62,558 long tons (53,094 tons raw and 9,464 tons of plaster of Paris) sent abroad compared with 23,979 tons in 1949, the previous peak year. The Hellenic Mining Co. new subsidiary, the Gypsum & Plasterboard Co., exported 50,094 tons of raw gypsum in 1950. The company was scheduled to place in operation in 1951 a modern stucco and plasterboard plant.[21]

Dominican Republic.—Considerable impetus was given to the Government-operated salt and gypsum industry in the Barahona area with the announcement that the Government would promote expansion of this industry. The Government Agricultural and Industrial Credit Bank floated a special bond issue to provide capital to liquidate pending accounts and to purchase modern mining equipment. Under study was a proposed railway to join the mining area with the port of Barahona, a distance of about 25 miles.[22]

Germany, West.—In the first 6 months of 1951 output of gypsum totaled 343,446 metric tons, of which 39,256 tons was exported, chiefly to the Scandinavian countries. Both production and exports were higher than in the first half of 1950.[23]

India.—Production of gypsum in India in 1950 was 202,118 long tons, of which 169,420 tons was mined in Rajasthan, particularly in the States of Bikaner and Jodhpur. The largest synthetic fertilizer factory in Asia, at Sindri, Bihar State, began production in October 1951. After a few months breaking-in period, it was expected to produce about 1,000 tons of ammonium sulfate a day, using the gypsum-ammonium nitrate process. It was claimed that this added capacity would make India self-sufficient in synthetic fertilizers. To meet the demand of this plant for crude gypsum, mining operations in Bikaner would be greatly expanded under the direction of local Government officials.[24]

United Kingdom.—An article in the trade press described the operation of the gypsum and alabaster industry in Staffordshire. The Fauld mine near Totbury produced gypsum, anhydrite, and alabaster. The formation being mined varied widely in quality from place to place, so selective mining was practiced, and careful grade control was maintained over the material taken. The alabaster works manufactured such articles as ash trays, book ends, vases, clock cases, lamp standards, etc., from large blocks, which sometimes weigh as much as 4 tons each, of high-grade alabaster. The manufacturing technique is described in detail.[25]

Helium

By H. S. Kennedy and P. V. Mullins

GENERAL SUMMARY

BUREAU of Mines helium-production plants in the southwestern part of the United States are the sole sources of commercial quantities of helium. The plants are situated at Amarillo, Tex.; Exell, Tex. (near Amarillo); Otis, Kans.; and Shiprock, New Mex.

Helium is produced by extraction from certain helium-bearing natural gases, which, in typical cases, contain about 1 to 2 percent helium. Production operations are conducted pursuant to the Helium Act approved September 1, 1937 (50 Stat. 885, 50 U. S. C. secs. 161, 163–166); and current regulations thereunder, approved December 3, 1949 (30 CFR 1).

In 1951 helium production totaled 112.0 million cubic feet compared with 81.4 million in 1950. About 70 percent of the helium produced is consumed by Federal agencies, principally by the Navy for use in antisubmarine patrol blimps. The balance of the helium produced is consumed by commercial companies, chiefly for use as the inert shielding medium for inert-arc welding. Helium may be purchased from many compressed-gas distributors in virtually all parts of the United States.

Field headquarters for the Bureau's helium production activities are maintained at Amarillo.

RESERVES

A discussion of helium-bearing natural-gas reserves in Minerals Yearbook for 1950 indicated that approximately 5 billion cubic feet of helium was available to the Bureau's helium plants at that time. Subsequent studies in the Channing area of the Texas Panhandle field, which serves the Exell Helium Plant, have increased the estimate of helium available from that source by more than 5 billion cubic feet, making a total of over 10 billion cubic feet available to the Bureau's plants at the end of 1951. Gas suitable for helium production also was available in other areas.

PRODUCTION

Table 1 gives helium-production statistics for Government plants from 1921–51, inclusive.

The Bureau's Exell plant, largest of the four plants, had been operated almost continuously since 1943 and produced a major portion of the helium required in the 1943–51 period. In 1951 the Exell plant produced about 60 percent of helium requirements. The balance was produced at the Otis and Amarillo plants. Helium production in 1951 was about 40 percent greater than in 1950 and about 100 percent greater than in 1949.

TABLE 1.—Helium production in the United States, 1921–51

Year	Plant	Cubic feet
1921—January 1929 [1]	Fort Worth, Tex., plant	46,088,787
1929 (April) [1]—1941	Amarillo, Tex., plant	131,614,437
1942	do	33,252,582
1943	All plants	116,307,437
1944	do	126,933,130
1945	do	94,733,744
1946	Amarillo and Exell, Tex., plants	58,236,385
1947	Exell, Tex., plant	70,297,700
1948	do	63,143,513
1949	do	55,165,482
1950	Amarillo and Exell, Tex., plants	81,394,416
1951	Amarillo, Exell, Tex., and Otis, Kans., plants.	112,047,244
Total 1921–51		[2] 989,214,857

[1] No helium was produced at Government helium plants in February or March 1929. The Fort Worth helium plant was shut down Jan. 10, 1929, and the Amarillo helium plant was not put into operation until April.

[2] Includes 88,272,100 cubic feet extracted at the Exell plant and injected into the Government-owned Cliffside gas reservoir, for conservation, in calendar years 1945–49 and 1951 (none stored in 1950).

The Exell and Amarillo plants, situated 30 miles apart, are connected by a pipeline that traverses the Government-owned Cliffside gas field, source of helium-bearing gas for the Amarillo plant. The pipeline permits transportation of helium between the plants and injection and storage in the Cliffside field of any helium produced at Exell and not needed to meet demand. In 1951, 4,908,300 cubic feet of helium was injected and stored in this manner.

The Navajo (Shiprock) plant was maintained in standby status throughout 1951.

SHIPMENTS

Helium production is geared to and virtually equal to shipments (demand), as there is only limited aboveground storage for helium at the production plants.

Helium is shipped at 1,800 to 2,400 pounds pressure in special railroad tank cars, automotive trailers, and standard compressed-gas cylinders. Cylinder shipments are made exclusively from the Amarillo plant because of its convenient location to motor freight facilities which handle most cylinder shipments.

The rapidly increasing demand for helium caused a corresponding increase in use of all types of shipping containers and threat of a definite shortage of them.

CONSUMPTION AND USES

Helium continues to find its greatest use as a buoyant gas for blimps and balloons employed by military agencies, commercial advertising companies, the Weather Bureau, and others. A close second, and rapidly increasing use is to provide the inert shielding medium in shielded-arc welding of aluminum, magnesium, stainless steel, Monel, copper, and other metals. Helium is being used also to provide the essential inert atmosphere required in producing and fabricating less common, but increasingly important metals, such as titanium and zirconium.

Digitized by Google

The increasing use and importance of all of the aforementioned metals, especially in the national defense program, accounts for much of the increase in helium demand.

Helium is used for a variety of other purposes. It is finding wide use by Federal and non-Federal agencies in research and experimental work in atomic energy, guided missiles, physical and chemical properties of materials at low temperature, and many other fields of investigation. Oil and gas companies obtain desired reservoir data by using helium as a tracer in natural gas injected for pressure maintenance and recycling purposes. Medical uses of helium-oxygen mixtures to relieve suffering from asthma and other respiratory ailments and as a component of anesthetics to reduce explosion hazards in operating rooms are common and generally well known.

PRICES

Federal agencies requisition helium from the Bureau of Mines at a price that represents their proportionate shares of the expenses incident to the administration, operation, and maintenance of the Government's helium plants and properties. In 1951 this price was about $12.50 per 1,000 cubic feet, f. o. b. production plants. The price of helium to non-Federal purchasers, at a helium plant selected by the Bureau, was $13.50 per 1,000 cubic feet, as established by regulations approved in December 1949. An additional charge of $2.00 per 1,000 cubic feet was made when helium was delivered in standard cylinders.

FOREIGN TRADE

Helium is not produced commercially outside the United States. It can be exported from the United States only upon application to the Secretary of State and upon receipt of a license authorizing exportation.

TECHNOLOGY

The Bureau of Mines conducts a small research program on helium production and utilization at laboratories in Amarillo, Tex.

Research in 1951 was directed primarily at solution of processing and operating problems arising from rapidly increasing helium demand, especially for high-purity Grade A helium, which is now required or preferred for almost all uses. Research was continued also on helium utilization, chiefly with regard to shielded-arc welding and assistance to industry in helium tracer projects to obtain data on oil and gas reservoirs.

Research-staff members are available for consultation on helium-utilization and gas-processing features of mutual interest to those in other industries.

Iron Ore

By Jachin M. Forbes

GENERAL SUMMARY

THE LARGEST output of iron ore in history was recorded in the United States for 1951. Mines were called upon to supply unprecedented tonnages and were able to do so as a result of extraordinary efforts supported by good labor-management relations during most of the year. Transportation facilities for ore from the Lake Superior district were taxed to capacity but failed to establish a new high seasonal ore movement via the Great Lakes owing in part to bad weather at the end of the season. Supplementary tonnages amounting to about 6 million tons were transported all-rail direct from mines in the Lake Superior district to lower Lake furnaces.

The strong demand for iron ore, which was related to rearmament and steel-expansion programs, stimulated widespread interest in undeveloped and idle iron-ore deposits. A number of new mines were being developed during 1951 as well as old mines expanded or reopened. Stockpiles of hitherto unsalable ore were subjected to concentration and increased the supply of usable ore, and numerous intermittent producers of brown ore from small deposits enjoyed a good year. The tax benefits authorized by the Internal Revenue Act of 1950 encouraged several large mining companies to plan construction of additional mills for an expanded production of beneficiated iron ore, including 10.5 million tons annual capacity of taconite concentrates.

Foreign trade was highlighted by initial receipts of ore from two major developments that are expected to be important in the prospective supply pattern of the United States. The Iron Mines Co. of Venezuela, a subsidiary of Bethlehem Steel Co., announced the arrival of the first shipload of Venezuelan ore from the Pao mine in April, and the Liberia Mining Co. also began shipments during 1951. Development proceeded apace toward early production from other new sources in Quebec-Labrador and Venezuela.

The St. Lawrence Seaway, which would greatly facilitate movement of iron ore from the Quebec-Labrador deposits, was again discussed extensively before Congress in 1951. New urgency was indicated as a result of the need for Canadian ore. However, delaying tactics used by opponents of this project continued to be effective. Canadian authorities announced that if the United States was not prepared to complete the Seaway as a joint effort, plans would proceed for an all-Canadian project.

Digitized by Google

Salient Statistics.—Usable iron ore produced from domestic mines totaled 115.9 million gross tons in 1951. An additional half million tons of byproduct ore obtained from treating pyrites brought the total to 116.5 million tons, 19 percent higher than 1950 and 10 percent higher than 1942, the highest year of previous record. Each of the producing districts increased production above 1950, with the Lake Superior district providing the greatest increase in quantity and Western States the greatest percentage increase. Nearly three-fourths of production was of direct-shipping grade, and the remainder was concentrated or sintered. Although the quantity of beneficiated ore increased substantially in continuation of the trend apparent for many years, the percentage of production that was treated dropped as a result of a larger increase in direct-shipping ore. Concentrated- or

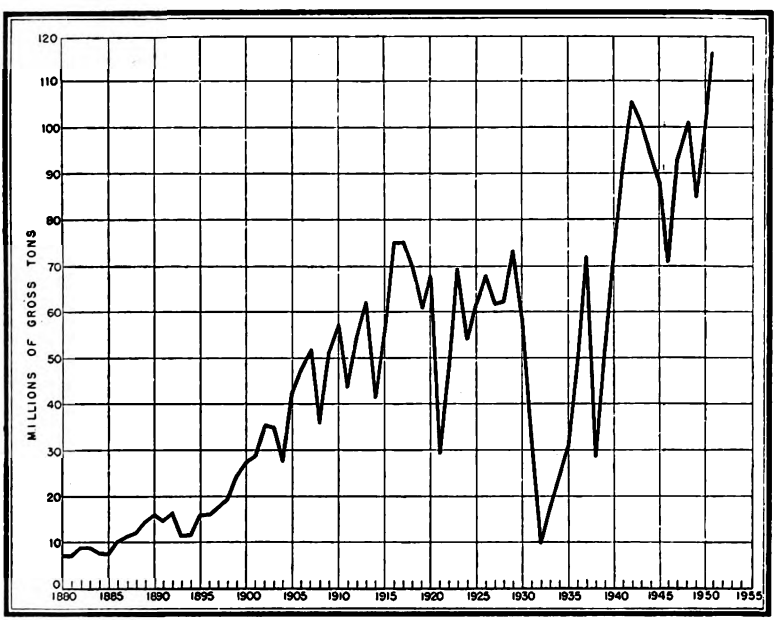

FIGURE 1.—Production of iron ore in the United States, 1880–1951.

sintered-ore production is limited by mill capacity and necessarily increases slowly, while the output of open-pit direct ore fluctuates in quick response to demand. The bulk of all production was of the hematite variety (Fe_2O_3) with only 10 percent of the usable product as magnetite (Fe_3O_4) and 3 percent brown ore ($Fe_2O_3 \cdot XH_2O$). No carbonate or siderite ($FeCO_3$) was produced separately, although East Texas brown ore includes some carbonate not differentiated statistically.

Shipments of iron ore did not differ substantially in quantity from production and increased a similar percentage above those of 1950. Reported value at the mines, on the other hand, increased 30 percent owing to higher prices as well as the larger tonnage. Average value per ton increased $0.47 to $5.46 in 1951.

Digitized by Google

Imports of iron ore increased again in 1951, with substantial assistance from new sources. One-third of the 23-percent increase over 1950 imports came from Venezuela, and one-fourth was attributable to increased receipts from Sweden. Nevertheless, Chile continued to be the leading supplier with 27 percent of the total. Exported iron ore went to Canada and Japan with only small lots to other destinations. Canada is normally a large user of United States ore; in turn, a substantial tonnage of Canadian ore is used in United States furnaces. In 1951 the export market again included Japan. The ore supplying this trade came from mines in California, Nevada, and Utah.

Consumption of iron ore was virtually all in iron and steel furnaces or sintering plants which merely treated the ore before consumption with untreated ores. The total reached a new high of 114.8 million tons including approximately one-half million tons for nonmetallurgical use. Thus, the supply of iron ore in 1951 exceeded requirements, and furnace stocks were greatly improved over the precarious position obtaining at the beginning of the year.

PRODUCTION AND SHIPMENTS

The output of crude iron ore, including ore to be beneficiated as well as direct-shipping grades, reached a new alltime high of 152.1 million gross tons in 1951. Of this total, 67.1 million tons or 44 percent was processed to obtain 25.7 million tons of concentrate and 4.9 million tons of sinter (an additional 18.4 million tons of sinter was produced at custom plants and consuming furnaces from iron-ore concentrates, fines, flue dust, mill scale, and other iron-bearing materials). Beneficiation at the mines included log washing, various gravity methods, magnetic separation, and agglomeration, principally by sintering. Direct-ore production totaled 85 million tons, some of which was crushed and sized before shipment. Byproduct cinder and sinter, a high-iron content residue from pyrites used in the

manufacture of sulfuric acid, accounted for 568,631 tons, part of which was sintered. In all, 116.5 million gross tons of usable iron ore, including byproduct ore and a small tonnage from Puerto Rico, was produced at domestic mines and mills in 1951. The total was 19 percent greater than 1950, as was the corresponding shipments total of 116.2 million tons.

The number of active mines increased appreciably during 1951, chiefly as a result of intermittent small operations of marginal character. However, the increase included several new mines of substantial size operated by established companies. Of the 289 mines recorded, 46 produced over 1 million tons of crude ore each. Minnesota, Michigan, and Alabama continued to produce the largest quantities, with 68, 12, and 7 percent, respectively, of the 115,936,041 tons of mine output. The Lake Superior district (Michigan, Minnesota, and Wisconsin) produced 93,946,990 tons or 81 percent of the total. Compared with 1950, this proportion was 0.7 percent lower, and consistent with the slightly smaller tonnage increase—18 percent for the district as compared with the 19 percent for the United States. Southeastern States (Alabama, Georgia, Tennessee, and Virginia) produced 8,587,408 tons or 7.4 percent of the total as compared with 7.7 percent in 1950; the tonnage increase was 14 percent. Northeastern States (New Jersey, New York, and Pennsylvania) produced 5,180,959 tons—4.5 percent of the total and 16 percent above the 1950 production. Western States achieved the largest percentage increase in 1951; the 8,181,465 tons of output was 40 percent greater than in 1950 and represented 7.1 percent of total usable ore production, as compared with 6.0 percent last year.

[4] Cinder and sinter obtained from pyrites treated in, but not necessarily mined in, States indicated.

PRINCIPAL MINES

The domestic iron mines producing over 500,000 gross tons of crude ore each in 1951 are listed in table 9. The order of listing is based on the tonnage of material mined before treatment and without respect to iron content; thus mines producing low-grade material that is subsequently processed to eliminate a large percentage of gangue material are considered comparable in size to mines producing similar tonnages of direct-shipping ore. In the Lake Superior district a number of mines producing from continuous ore bodies have been consolidated into single operations as small pits have grown into large excavations. These are now identified by group, and account for the disappearance from the list of some large producers in past years.

Forty-six mines reported an output exceeding 1 million tons each in 1951 and together supplied 64 percent of total crude-ore production. Two mines listed in this group in 1950 reduced output below the million-ton level and were replaced by 10 mines listed below that level in 1950. Of the 46 mines, 31 were in Minnesota, 4 each in Alabama and New York, 2 in Utah, and 1 each in California, Michigan, Pennsylvania, Texas, and Wisconsin; 37 were open-pit mines, 6 under-

Digitized by Google

ground, and 3 combined operations. In 1950, 38 million-ton mines produced 59 percent of the total crude-ore output.

Forty-three mines, producing 500,000 to 1,000,000 tons each, supplied 19 percent of crude ore produced in 1951. Of these, 23 were in Minnesota, 11 in Michigan, 4 in Alabama, and 1 each in Missouri, New Jersey, Utah, Wisconsin, and Wyoming. Eighty-three percent of all crude iron ore mined in the United States during 1951 came from the 89 mines listed in table 9.

SINTER

United States production of sinter for consumption in iron and steel furnaces during 1951 increased 21 percent above the 18,740,217 tons in 1950, reflecting new capacity installed during 1950 and 1951. Iron-bearing materials consumed in the manufacture of sinter included 16,795,596 tons of iron ore, 5,110 tons of manganiferous ore, 8,784,589 tons of flue dust, 457,277 tons of mill cinder and roll scale, and 640,340 tons of pyrites cinder. Included in the above figures but not identified were at least 20,000 tons of aniline sludge. The total, 26,682,912 tons, resulted in a conversion yield of 85 percent, 4 percent less than in 1950.

Digitized by Google

Sintering plants at mines in 5 States produced 4,945,278 tons (22 percent of the total), and plants at blast furnaces and custom mills in 14 States produced 17,697,754 tons (78 percent).

TABLE 10.—Production and consumption of sinter in the United States in 1951, by States, in gross tons

State	Sinter produced	Sinter consumed	
		In blast furnaces	In steel furnaces
Alabama	1,430,441	1,670,198	87,590

REVIEW OF LAKE SUPERIOR DISTRICT

Production and Shipments.—Responding to extraordinary demand, mines and mills in Michigan, Minnesota, and Wisconsin produced 93,946,990 gross tons of usable iron ore (containing less than 5 percent manganese) in 1951, establishing a new record high and exceeding the previous high of 1942 by 3 percent. The Mesabi range alone produced 73,574,908 tons (63 percent of all domestic usable ore) and an equal percentage of all direct-shipping grades. The 6 ranges together supplied all of the Lake Superior production, with the exception of 452,405 tons of brown ore from mines in Fillmore County, Minn., which is not considered part of the true Lake Superior district. Deducting brown ore from the States' total above, the Lake Superior district produced 93,494,585 tons, or 80 percent of the total usable output. In addition, 1,007,611 tons of ore containing (natural) 5 percent or more manganese was produced, principally from the Cuyuna range. Including both Fillmore County and manganiferous production, the entire district output was 94,954,601 tons. The corresponding shipments total was 94,485,801 tons, of which 93,069,033 tons was iron ore from the 6 ranges, 452,235 tons was brown ore from Fillmore County, and 964,533 tons was manganiferous ore.

Railroad weights of iron and manganiferous ores shipped from United States mines in the Lake Superior district, as reported by the Lake Superior Iron Ore Association, totaled 94,488,009 tons, of which 86,952,792 tons was transshipped via the Great Lakes water route and 7,535,217 tons went to furnaces via all-rail. Of the all-rail shipments, about 6,000,000 tons went to furnaces normally supplied by the water route. This was an emergency measure of proportions that may never again be equaled.

Digitized by Google

Iron ore from Canadian mines in the Lake Superior region is not included in the above figures. Shipments from these mines in 1951 totaled 2,510,934 gross tons—1,184,210 tons from the Helen mine in the Michipicoten district and 1,326,724 tons from Steep Rock mines in the Atikokan district. This ore, also, normally moves over the Great Lakes; however, in 1951 a total of 383,581 tons moved all-rail to consuming centers.

The 266 vessels of the Great Lakes ore-carrier fleet had a trip capacity of 2,861,230 gross tons on May 15, 1951.[1] By November 2, new ships had joined the fleet; 6 more vessels were scheduled to be in service by May 1952.[2] Thus it was apparent that the transportation bottleneck for Lake Superior iron ore was about to be broken.

The 1951 navigation season began at Escanaba, Mich., on April 6 with departure of the steamer, *Joseph Sellwood*. Upper Lake ports opened within a week, Marquette, Mich., on April 9 and Duluth, Two Harbors, and Superior, Minn., on April 11. Unlike the previous spring, when ice and weather conditions seriously hampered early vessel movements, the 1951 season began with heavy shipments totaling 6,121,856 tons from United States ports in April compared with only 348,804 tons in April 1950. Weather did not seriously affect ore movements until November, when early cold waves struck the upper Lake area, slowing loading and causing some ships to remain in the harbor for a break in the blizzard. The effect was to reduce November shipments by water 1,261,100 tons below the previous November. However, stocks of ore at lower Lake furnaces were much improved compared with 1950, and the urgency had been dissipated by near-record water shipments, supplemented by all-rail shipments.

Technologic Trends.—Emphasis in the Lake Superior district during 1951 was on expanded total output; however, within the demand for greater tonnage was an urgent need for increased mill capacity to process crude ores. The first large steps toward producing commercial quantities of taconite concentrates were made, and widespread attention was given to more efficient means of treating the so-called wash ores. Variations of the heavy-medium process gained increased acceptance for ores of suitable character, and hydraulic applications were devised for some types of fine-grained ores. Flota-

Digitized by Google

tion was under consideration for commercial-scale production, and plans were being made to sinter large quantities of Mesabi soft ore.

Mining methods in use on the Menominee range were described in an article which included an informative table.[3] Of 17 mines listed, 15 were underground, 11 used sublevel stopes, 1 used a combination of sublevel and shrinkage stopes, 1 used shrinkage stopes, and 2 were under development. The table also listed shaft depths, number of men employed, methods of tramming, crushing, stockpiling, and shiploading, pumping capacity, skip size, and distance between levels.

Analyses.—Table 12 shows average analyses of all ore shipped from the Lake Superior district iron ranges, 1946–51. The gradual decline in average quality was apparent again in 1951; iron content was down 0.13 percent from 1950, with slight increases in silica and moisture.

Reserves.—Taxable and State-owned reserves of iron ore in Michigan and Minnesota are given in tables 13 and 14. It will be noted that Michigan reserves have increased, while Minnesota reserves have declined, except for 1950. This is partly explained by the fact that the bulk of Michigan's reserves is underground while Minnesota has a preponderance of ore in surface deposits. Underground development to prove reserves is more expensive and the tonnages are not amenable to visual estimates, however conservative. In either case, it should be remembered that taxable reserves do not represent the total tonnage that may be expected to become available.

MINING BY STATES

Alabama.—As the largest iron-ore-producing State outside the Lake Superior district, Alabama supplied 7 percent of all usable output in 1951. Production was 12 percent above 1950 but 8 percent below the record high of 1942.

Eighty-seven percent (7,107,376 tons) of the State production was red hematite from 10 major mines in Jefferson County. A small tonnage of soft red ore was also produced. Brown-ore concentrates, principally from mines in the Russellville area of Franklin County, totaled 1,041,838 tons or 13 percent of the State output. Virtually all of the red ore was produced from mines owned and operated by the local steel companies and merchant pig-iron producers. Brown ore was produced from numerous small surface operations; however, in the Russellville area, Sloss-Sheffield Steel & Iron Div., United States Pipe & Foundry Corp., Shook & Fletcher Supply Co., and the Schroeder Co. are major suppliers.

Alabama red ores are partly self-fluxing, with a low iron content, and brown-ore concentrates plus high-grade ore from the Lake Superior region and foreign sources are used for blending purposes to enrich the blast-furnace charge. Thus, Alabama consumed 9,859,720 tons of iron ore, 20 percent more than was produced in the State.

Arkansas.—The Magnet Iron Co., Little Rock, Ark., shipped magnetite selectively mined near Butterfield in Hot Spring County. In addition, a small lot of magnetite was shipped from Lawrence County.

California.—Kaiser Steel Corp. shipped mixed hematite and magnetite from the Eagle Mountain mine in Riverside County to its furnaces at Fontana, and 15,600 tons was shipped from the Bessemer mine in San Bernardino County for export to Japan.

Georgia.—Producers of brown-ore concentrates in Georgia increased output 77 percent over 1950 as a result of a relatively firm market. A laboratory set up during the year at Cartersville permitted ore analyses before shipment for some operators and reduced the risk of losses due to shipments failing to meet specifications. Most of the usable ore produced came from the vicinity of Cartersville in Bartow County and Cedartown in Polk County.

Michigan and Minnesota.—*See* Review of the Lake Superior District.

Digitized by Google

Missouri.—The Ozark Ore Co., a subsidiary of The M. A. Hanna Co., operated the Iron Mountain mine in St. Francois County as a combined open-pit-underground producer in 1951. The mine is converting to underground methods, and 94,850 of the total 515,611 tons of crude ore supplied by the mine came from the new shaft. Gravity methods are used to concentrate the crude ore to a usable product. During the year many showings of brown ore in Missouri were considered for commercial possibilities, and at least five companies shipped ore from various localities.

Nevada.—The iron ore export market to Japan stimulated the opening of several deposits in Nevada during 1951. Small shipments had been made for several years from a Union Pacific property of particularly high grade in Pershing County. However, a relatively firm market caused interest in other showings nearby, including the Segerstrom-Heiser deposit operated by the Dodge Construction Co. and the Buena Vista deposit operated by the Mineral Materials Co. The Phelps-Stokes deposit in Nye County was supplying a small tonnage of iron ore for nonmetallurgical use by the Standard Slag Co. and later expanded production to include exports. In Eureka County, Simplot Iron Mines Inc. developed the Modarelli deposit and exported a substantial tonnage in 1951.

New Jersey.—Established iron mines in Morris and Warren Counties increased 1951 production of magnetite lump ore and concentrates 12 percent above 1950. No shipments were reported from the Ringwood mine in Passaic County. However, a small tonnage was hoisted for test runs in the rehabilitation of the concentrating mill. The Peters and Cannon mines and the concentration mill which comprise the Ringwood properties were purchased from the Government by Ringwood Iron Mines, Inc.

New Mexico.—The Hanover-Bessemer mine in Grant County continued production of magnetite in 1951 and was joined by two small producers in Lincoln County.

New York.—Adirondack magnetite lump ore and concentrates were produced from four localities in 1951. Republic Steel Corp. produced from the Fisher Hill mine and the New Bed-Harmony-Old Bed shafts at Mineville in the Port Henry area, Essex County, and the combination open-pit underground Chateaugay mine at Lyon Mountain, Clinton County. National Lead Co. produced coproducts of iron-ore concentrates and ilmenite from the titaniferous ore body at Tahawus, Essex County. Jones & Laughlin Ore Co. produced concentrates and sinter from the Benson open pit near Star Lake in St. Lawrence County; and the Clifton mine, also in St. Lawrence County, operated by the Hanna Coal & Ore Corp., produced sintered magnetite concentrates. This mine was scheduled for abandonment owing to exhaustion of the ore body. The Clinton Metallic Paint Co. continued to produce hematite for use as pigment from mines in Oneida County.

Digitized by Google

Pennsylvania.—The Bethlehem Steel Co. Cornwall mines and Lebanon concentrator increased production of concentrates, sinter, and pellets 9 percent over 1950, notwithstanding the fact that Cornwall is one of the oldest iron-ore producers in the United States. Rarely during recent years in the United States has a new iron-ore deposit been discovered. Usually, known occurrences are investigated for commercial possibilities. However, modern geophysical exploration revealed a magnetic anomaly of large proportions near Morgantown, Pa., which was later proved by diamond core drilling to be a commercial-grade iron-ore body. The ore was located at a depth of 1,500 to 3,000 feet below the surface, and plans were announced to sink 2 shafts immediately. During the development of the mine, which is expected to require 2 to 3 years, a beneficiating plant will be constructed to produce concentrates of 60 percent-plus iron content.[4] Consumers of iron ore in Pennsylvania are expected to use large quantities of imported ores in the future, most of which will come through the ports of Philadelphia and Baltimore. Present facilities for handling these materials are inadequate, and ore-unloading docks were being constructed in Philadelphia by the Pennsylvania Railroad.[5] In Baltimore, Md., the new unloading dock of the Baltimore & Ohio Railroad was completed and put into service.

Tennessee.—Several small lots of brown ore were shipped from Tennessee deposits in 1951, with prospects for increased output in 1952.

Texas.—Brown-ore deposits in east Texas supplied a slightly smaller tonnage of usable ore than in 1950. This material contains some carbonate, not differentiated in production statistics, which requires calcining after concentration by hydraulic methods. Production for metallurgical use was by the Lone Star Steel Co. and the Sheffield Steel Corp. a subsidiary of Armco Steel Corp.

Utah.—Established producers in Iron County again increased production, which in 1951 exceeded the previous year by over 1.5 million tons, or 51 percent. The Desert Mound mine of the Columbia-Geneva Steel Division, United States Steel Corp., produced 422,000 tons of the increase, which, along with increases at other mines near Cedar City accounted for much of the 2-million-ton increase attributed to Western States.

Virginia.—The American Pigment Corp. continued to produce iron oxides for use as a pigment in making paint.

Wisconsin.—*See* Review of the Lake Superior District.

Wyoming.—The Sunrise mine in Platte County increased output 25 percent over 1950. This ore, classified as direct-shipping grade, undergoes partial treatment after shipment to the Pueblo plant of the Colorado Fuel & Iron Corp.

CONSUMPTION

Consumers of iron ore reported the use of 114.8 million gross tons during 1951, a new record high consumption total that exceeded the previous record (1950) by 8 percent. Blast furnaces used 80 percent of the total, steel furnaces 5, sintering plants 14, and ferroalloy furnaces, cement plants, and pigment and other uses less than 1 percent. The increasing proportion of iron ore going through the sintering

Digitized by Google

process before final consumption in both iron and steel furnaces is of particular interest. Additional information on this phase of the industry is given in the Sinter section of this chapter. Iron-ore consumption by State and use is shown in table 16.

[1] State totals include only tonnages shown. Other tonnages included with "Undistributed."
[2] Included with "Undistributed."
[3] Includes States indicated by footnote 2 plus the following: For cement, Arkansas, Arizona, Florida, Idaho, Iowa, Kansas, Missouri, Montana, Oklahoma, Oregon, South Dakota, and Washington; for paint, Georgia, North Dakota, and Wisconsin; and a small tonnage from Nevada as ship ballast and in making refractories.

STOCKS

Mine stocks of usable iron ore on hand December 31, 1951, are shown in table 17. Minnesota, Michigan, and New York mines held the bulk of this ore—44, 35, and 10 percent, respectively, of the total. Including Wisconsin, the Lake Superior district held 82 percent of all mine stocks. Consuming plants reported 40,952,788 gross tons of iron ore on hand at the end of 1951, including 648,527 tons of sinter. Any iron-ore balance calculated from domestic shipments, imports, exports, consumption, and stock changes should consider also stocks of ore at Lake Erie ports (see below) and a reasonable allowance for ore in transit. Additional difficulties involved in obtaining a balance concern recycled materials such as flue dust, mill cinder, and roll scale blended with iron-ore concentrates and fines in the manufacture of sinter.

Stocks at Lake Erie Ports.—Iron ore on Lake Erie docks January 1, 1952, totaled 6,395,884 tons. A month earlier, near the close of the Lake navigation season, these stocks were 6,841,157 tons, according to reports of the Lake Superior Iron Ore Association. During the 4 months December 1, 1951–April 1, 1952, the total was reduced

TABLE 17.—Stocks of usable iron ore at mines, Dec. 31, 1950–51, by States, in gross tons

State	1950	1951	State	1950	1951
Alabama	54,609	44,389	Pennsylvania	5,357	8,153
California	91,346	107,394	Texas	54,132	103,055
Michigan	1,876,036	1,985,840	Utah	60,459	149,379
Minnesota	2,324,731	2,445,286	Virginia	576	1,081
Missouri		110	Wisconsin	124,886	137,000
Nevada		32,317			
New Jersey		815	Total	5,725,569	5,599,466
New York	1,133,437	584,647			

3,471,872 tons to 3,369,285 tons. It should be noted that some furnaces using Lake Superior ores received substantial tonnage via all-rail from Lake Superior mines during this period.

PRICES [6]

The average value per gross ton of iron ore f. o. b. mines and mills was $5.46 in 1951 compared with $4.99 in 1950, and $4.50 in 1949. Table 18 gives the average value at mines of the different types of product and varieties of ore for each of the producing States, except where there are fewer than three shippers of a certain class of ore in a State and where permission has not been given to publish the value. These data are taken directly from statements of producers and probably represent the commercial selling prices only approximately. In general, the delivered cost is given less transportation costs to the consuming plant. In the Lake Superior district the mine value is the Lake Erie price less freight from mines to lower Lake ports. This value appears to be applied also to ore that is not sold on the open market.

Prices of Lake Superior Iron Ore.—Lake Erie base prices for Lake Superior iron ores were effective December 2, 1950, for the 1951 season. An increase of $0.60 per ton over 1950 was accorded for each ore classification which were quoted for 1951 as follows: Old Range Bessemer, $8.70; Old Range non-Bessemer, $8.55; Mesabi Bessemer, $8.45; Mesabi non-Bessemer, $8.30; and High-Phosphorus, $8.30.[7] These prices were for ore delivered at lower Lake ports and based on 51.5 percent iron content (natural) for all grades. Bessemer grades carry 0.045 percent (max.) phosphorus (dry), and High-Phosphorus grades exceed 0.18 percent phosphorus (dry). Premiums and penalties are applied for variations in analyses and physical structure.

Freight Rates.—Transportation charges on iron ore were increased effective August 28, 1951, with interim increases from April 4, 1951, by I. C. C. ex parte 175 of August 27, 1951. The interim changes did not affect rates from upper Lake ranges to lower Lake ports but afforded increases ranging between $0.05 and $0.11 per ton for rail rates to consuming centers from lower Lake ports. Comparing 1950 rates from the Mesabi range to Pittsburgh with 1951 rates after the I. C. C. order, rail rates to upper Lake ports increased $0.063 to $1.113; vessel rates increased $0.012 to $1.662; and rail rates to Pitts-

TABLE 18.—Average value per gross ton of iron ore at mines in the United States, 1950–51

[Exclusive of ore containing 5 percent or more manganese]

State	1950							1951						
	Direct			Concentrates				Direct			Concentrates			
	Hematite	Brown ore	Magnetite	Hematite	Brown ore	Magnetite	Sinter	Hematite	Brown ore	Magnetite	Hematite	Brown ore	Magnetite	Sinter
Mined ore:														
Alabama	$3.88				$3.11		(1)	$4.08				$3.29		(1)
Georgia	(1)				3.34							3.74		
Michigan	5.64							6.01			$5.10			
Minnesota	4.72			$5.09	(1)	(1)	(1)	5.19			5.44	(1)	(1)	(1)
New Jersey			(1)			$9.32				(1)			$11.86	
New York			(1)	(1)		7.50	$10.04			(1)	(1)		7.02	$11.71
Pennsylvania						(1)	(1)						(1)	(1)
Utah			$1.85							$2.19				
Other States [2]	4.44	$3.50	3.19	7.92	3.09	3.23	(1)	4.91	$11.04	6.52	8.44	5.51	3.64	(1)
Average, all States	4.82	3.50	2.47	5.12	3.42	8.54	8.52	5.23	11.04	3.54	5.46	4.44	9.37	10.47
Byproduct ore: [3]														
Colorado														
Michigan														
Delaware														8.20
Tennessee							7.55							
Virginia														

[1] Included with average for all States.
[2] Includes Arkansas, California, Missouri, Nevada, New Mexico, Tennessee, Texas, Virginia, Wisconsin, Wyoming, and Puerto Rico.
[3] Cinder and sinter obtained from pyrites treated in, but not necessarily mined in, States indicated.

burgh increased $0.1134 to $2.0034. The overall increase totaled $0.1884 per ton, bringing transportation charges to $4.7784. By adding $0.1434 Federal transportation tax and $5.137 average value for Mesabi direct-shipping ore at the mines, the Pittsburgh value for the bulk of Lake Superior ore was calculated at $10.06 per gross ton. The considerable tonnage of ore moved all-rail from Lake Superior mines to lower Lakes consuming centers during 1951 was affected by increases for the interim period, April 4, to August 28 and afterwards. Rates from the Mesabi range to Pittsburgh were $5.63 per ton to April 4, 1951, $5.72 April 4 through August 27, and $5.9678 after August 27, 1951. The difference in rates for ore over the water route after August 27, 1951, as compared with all-rail rates equaled $1.1894 per ton.

Additional details on rates between points and component charges were published.[8]

FOREIGN TRADE [9]

The origin, tonnage, and value of iron ore imported and exported, 1949–51, are shown in tables 19 and 20. Imports increased 23 percent over 1950 and continued the trend toward greater use in the United States of foreign iron ores. Although initial shipments of 635,416 tons were received from Bethlehem Steel's El Pao mine in Venezuela, the increase does not reflect the upsurge expected in imported ore

[8] Lake Superior Iron Ore Assoc., Revised Freight Rate Table: Cleveland, May 28, 1951, and Sept. 1, 1951.
[9] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Digitized by Google

when shipments begin from the Quebec-Labrador and Cerro Bolivar developments. Chile maintained its position as leading foreign supplier, with 27 percent of total receipts in 1951. Sweden was a close second, with 25 percent, followed by Canada, 20 percent; and Brazil, 10 percent. Of 12 other sources (together supplying the remaining 18 percent), Venezuela exceeded one-half million tons and Algeria approached that level, leaving 10 of the 16 sources supplying less than 8 percent of all receipts. Exports were highlighted by Japan's return to the market for United States iron ore. The 954,842

TABLE 19.—Iron ore imported for consumption in the United States, 1949–51, by countries, in gross tons [1]

tons shipped to Japan and a 31-percent increase over 1950 in iron ore to Canada accounted for virtually all of the 68-percent increase in exports. Seven other countries received 925 tons in total.

BENEFICIATION

Shipments of beneficiated iron ore increased 15 percent over 1950. However, owing to a larger increase in direct shipments, the proportion of treated ore dropped to 26.5 percent compared with 27.5 percent in 1950. Table 21 shows tonnages of beneficiated iron ore, total shipments, and proportion of beneficiated ore since 1925.

Plans of the Erie Mining Co., Reserve Mining Co., and Oliver Iron Mining Div., United States Steel Corp., for the construction of taconite-beneficiation facilities proceeded during 1951. Reserve Mining Co. highlighted the taconite-development program with the announcement of a decision to construct a commercial plant of 2.5 million tons annual capacity for finished product. Mining and crushing facilities will be at Babbitt, Minn., with a new railroad 47 miles to Beaver Bay where the concentrating plant and ore-loading docks will be constructed.[10] Three contracting companies have combined and contracted to build the project managed by Oglebay, Norton & Co. for Reserve Mining Co. Plans included provisions to enlarge the plant as required to 10 million tons annual capacity. Ultimate cost of the initial phase was expected to exceed $75 million.[11] Oliver began its development program in 1950 with the construction of an agglomerating plant at Virginia, Minn. On May 17, 1951, ground was broken for the construction of a 500,000-ton taconite-beneficiation pilot plant at Mountain Iron, Minn. This company's program is long range and comprehensive, including research on various phases of taconite production, as well as treatment of high-grade fine ores and presently treated ores.[12] Erie Mining Co. continued to operate its pilot plant for concentrating and agglomerating taconite at Aurora, Minn., while preparing plans for the construction of commercial-scale facilities.

Michigan low-grade iron deposits, comparable in some respects to Mesabi taconite, were scheduled for increasing attention. Cleveland-Cliffs Iron Co. and Ford Motor Co. announced plans to construct a plant on the Marquette range at Humboldt, Mich., capable of producing 200,000 tons of concentrate annually. The product will be sintered at Detroit initially, but plans included possible agglomeration before shipment when proved feasible.[13] Of particular interest is the fact that Michigan low-grade ores are nonmagnetic, requiring entirely different beneficiating methods than magnetic taconite. Flotation will be used at Humboldt and for the first time in an iron-ore operation larger than laboratory scale. Results of the operation will carry substantial significance relative to the possibility of using flotation methods on other fine-size nonmagnetic ores.

Eastern magnetite produced in New Jersey and New York carries a nonmagnetic component, termed "martite," disseminated with the magnetite. In some deposits it constitutes a substantial percentage

Digitized by Google

of the ore, which is lost if only magnetic methods are used. Wilfley tables have been used extensively; but to improve recovery, Jones & Laughlin Ore Co. was installing at its Benson Mine a production-scale bank of Humphrey spirals late in 1951.[14] These wet-gravity concentrators are operating successfully on fine-size material in Minnesota and Michigan.

Heavy-medium separators are finding new application in Alabama in the recovery of brown ores failing to respond to washing methods, and new variations in heavy-medium-type equipment have appeared in the Lake Superior district. In general, this type of treatment has proved most satisfactory for beneficiating ore in which the iron-bearing particles are free in sizes between ⅛ inch to 3 inches. Sizes smaller than ⅛ inch not responding to magnetic separation constitute a major beneficiation problem and are receiving attention from research efforts. Recent developments in heavy-medium methods were described.[15]

TABLE 21.—Beneficiated iron ore shipped from mines in the United States, 1925–29 (average) and 1930–51, in gross tons

[Exclusive of ore containing 5 percent or more manganese]

1940	12,925,741	75,198,084	17.2				

EMPLOYMENT

The average number of workers employed at iron-ore-producing mines and mills in 1951 increased 9 percent over 1950, according to preliminary estimates. The total man-hours worked was estimated at 75,120,000, an increase of 14 percent, which compares with the 19-percent production increase. The indicated average output of usable ore per man-hour was 1.557 tons (115,936,041 tons of iron ore plus 1,007,611 tons of manganiferous iron ore divided by estimated man-hours) compared with 1.492 tons in 1950 and 1.378 in 1949.

The above data and table 22 include, in the Lake Superior district, manganiferous ore, which the trade considers a special grade of iron ore.

WORLD REVIEW

World production of iron ore, 1946–51, by countries, is shown in table 24. The 1951 estimates indicate an increase over 1950 of 19 percent, much of which was attributable to the United States, but a general rise was apparent throughout the world.

CANADA

Much of the information in this section is from Preliminary Report on Mineral Production, 1951, of the Dominion Bureau of Statistics, Department of Trade and Commerce, Ottawa.

Iron-ore production and shipments rose from 3,271,000 metric tons in 1950 to 4,297,000 tons in 1951, an increase of 31 percent and a new all-time record high for Canada, but small when compared with the tonnages expected within the next decade.

British Columbia.—The Argonaut Mining Co. Ltd., a subsidiary of Utah Construction Co., together with an affiliated operation, produced and shipped to Japan 109,000 metric tons of iron-ore concentrates from deposits on Vancouver and Texada Islands.

Labrador-Quebec.—Development of major iron deposts continued in 1951. Progress was detailed in an address by W. H. Durrell, general manager of the Iron Ore Co. of Canada, in an address delivered before the Hamilton branch, Engineering Institute of Canada, January 19, 1952. Durrell emphasized that development was on schedule and that initial shipments could be expected "not later than the late summer of 1954." Describing the railroad under construction and its projected operation, he said:

> Loaded trains will consist of 115 cars, 14,000 trailing tons hauled by locomotives of 6,000 h. p. Tentative running times are 14 hours for loaded trains and 12 hours for empty trains. To handle 10,000,000 tons in the operating season we will be required to operate approximately seven trains in each direction per day. The operation will require 55 diesel units, 20 cabooses, 2,400 ore cars (95 tons), and for construction and future maintenance, in addition to the above, we require 175 ballast cars, 50 boarding cars, 20 air dump cars, 100 flat cars, 15 tank cars, and 20 box cars.

Newfoundland.—The Wabana iron mines produced 1,622,000 metric tons of iron ore in 1951 and completed mechanization of the operation. Reserves are large in this bedded deposit of fossiliferous hematite. However, the market is limited to works having facilities for smelting high-phosphorus ores.

Ontario.—Steep Rock iron mines in the Atikokan district produced 1,348,000 metric tons of iron ore in 1951. Development continued toward the objective of 100 million tons of delineated reserve and eventual annual production of 10 million tons. The more immediate objective was an output rate of 3 million tons by 1955 from Errington open-pit and underground mines and the Hogarth open-pit. Algoma Ore Properties, Ltd., produced and sintered an estimated 1,218,000 tons of iron ore from the Helen mine which, with the Atikokan output, totaled 2,566,000 tons for Ontario, an all-time record high, with an increase of 16 percent over 1950. At Marmora, Hastings County, Ontario, the Bethlehem Steel Co. was exploring magnetite deposits of the Adirondack type; and in the Michipicoten district near Algoma's Helen mine, the Jalore Mining Co. was drilling siderite deposits on property owned by Frobisher, Ltd.

OTHER COUNTRIES

Brazil.—The lumpy iron ore, which constitutes most of Brazil's iron-ore exports, is a top-grade product greatly in demand for consumption in open-hearth steel furnaces. It commands the highest prices, which limit to some extent the magnitude of exports to the United States as well as other countries. In 1951 Brazil produced 2,555,000 metric tons of iron ore, of which the United States received 1,054,000 tons. Not all of the production was of open-hearth grade, a substantial tonnage having been consumed in domestic blast furnaces.

Chile.—The Tofo mine operated by Bethlehem Chile Iron Mines Co. produced 3,252,000 metric tons of iron ore, of which 2,812,000 tons moved to the United States.

Liberia.—After several years of development work, including the construction of a railroad and dock facilities, the Liberia Mining Co. shipped its first boatload of open-hearth-grade iron ore to the United States in June 1951. From surface deposits at Bomi Hills, 45 miles from Liberia's capital and port, Monrovia, the company expects to export about 1 million tons annually. Total receipts of Liberian ore in the United States during 1951 were 111,890 metric tons.

Peru.—A potential source of iron ore for United States furnaces was planned for development by the Utah Construction Co. of San Francisco.[16] The contract signed between the Peruvian Government and Utah Construction Co. provided a 20-year mining concession with an agreement to supply about 300,000 tons per year to an electric furnace not yet installed at Chimbote, 300 miles north of Lima. The deposit is some 300 miles south of Lima but only 15 miles from the coast.

Sweden.—Iron-ore production increased 16 percent to 16,111,000 metric tons in Sweden during 1951. The United States received 2,561,000 tons, and the remainder went to domestic and European furnaces. The Kiruna, Malmberget, and Grangeburg deposits were discussed.[17]

Venezuela.—The Pao iron-ore deposit 30 miles from San Felix on the south bank of the Orinoco River began shipments in 1951 after 15 years of exploration and development. Operated by the Iron Mines Co. of Venezuela, El Pao will supply ore to Bethlehem Steel's furnaces and eventually supplant ore now coming from Chile. Although production began in 1950, the first boatload of ore arrived at Sparrows Point, Md., on Bethlehem's S. S. *Bethore*, March 22, 1951. Production totaled 1,270,000 metric tons in 1951, and receipts at Sparrows Point were 646,000 tons. This source is one of the important new deposits scheduled to supply the United States expanding requirements for iron ore.[18]

A larger Venezuelan deposit, Cerro Bolivar is under development by the United States Steel Corp. and is expected to begin shipments before 1955.[19]

Iron and Steel

By Norwood B. Melcher, Jachin M. Forbes and James C. O. Harris

GENERAL SUMMARY

PRODUCTION of steel in the United States in 1951 reached an all-time high of over 105 million net tons. For the first time in the history of this country, the production exceeded rated capacity on an annual basis. The percentage of capacity for 1951 was 100.9; the previous high was 98.1 percent in 1943. The major factors that contributed to this high production rate were the 4-percent capacity increase during the year, not reflected in the high operating rate; the decrease in charging and rebuild time for furnaces; improved refractories; the jet tapper; and the use of oxygen in the open-hearth bath.

Bethlehem Steel Corp. led all companies in net capacity increase in 1951, with an 800,000-ton gain after subtracting 240,000 tons of discontinued Bessemer capacity. United States Steel Corp. was second with a gain of 774,000 tons. Year-end plans called for a 120-million-ton capacity at all United States plants by the end of 1953. This would be an increase of about 20 million tons over December 31, 1950. United States Steel Corp. planned the greatest single capacity

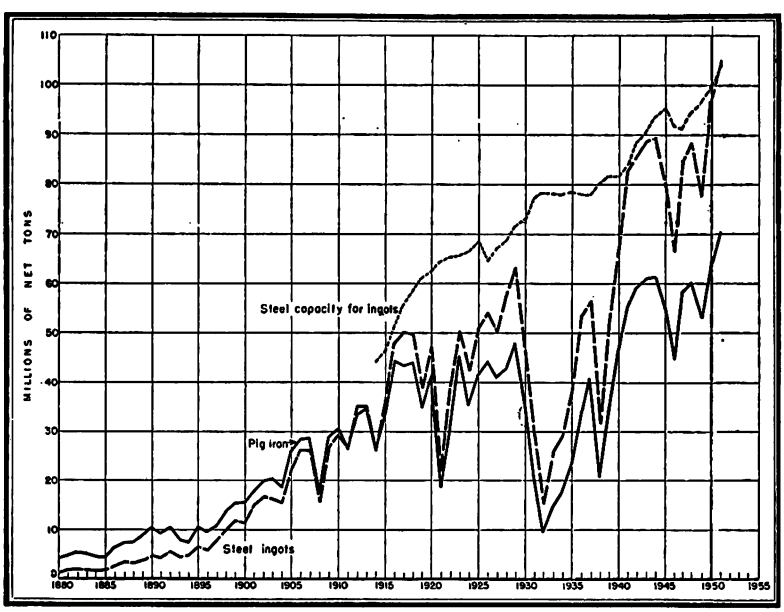

FIGURE 1.—Production of pig iron and steel ingots and steel capacity for ingots, in the United States, 1880–1951.

Digitized by Google

increase in 1952, with 1.8 million tons at its Morrisville, Pa., Fairless works; 500,000 tons at its Fairfield, Ala., works; and smaller increases at other plants.

Among the various industries receiving steel, the automotive industry showed the greatest change in receipts of steel. In 1951, during which passenger-car output dropped 20 percent (although truck production held its own), that industry received 16.7 percent (12,982,356 tons) of all steel shipments compared with 20.4 percent in 1950 and 19.4 percent in 1949. The rail-transportation industry, with freight-car loadings the greatest since 1948, increased its proportion of total shipments of steel received from 6.1 percent in 1950 to 7.4 percent in 1951. Ordnance and other military industries received 1.5 percent of the total shipments in 1951 compared with 0.3 percent in 1950, while the proportion received by the shipbuilding and marine-equipment industry more than doubled (1.1 percent compared with 0.5 percent in 1950).[1]

According to the records of the United States Department of Commerce, the total weight of semimanufactured and manufactured steel products exported exceeded the 1950 figure. Among such products, exports of steel ingots, blooms, billets, slabs, sheet bars, iron bars, concrete-reinforcing bars, iron and steel (uncoated), and wire nails more than doubled. Exports of welded galvanized pipes and tubes decreased considerably. Exports of all structural shapes combined increased, but those of fabricated structural shapes decreased somewhat.

TABLE 1.—Salient statistics of iron and steel in the United States, 1947–51, in net (short) tons

	1947	1948	1949	1950	1951
Pig iron:					
Production	58,327,231	60,073,140	53,323,142	64,499,983	70,277,938

Stainless	519,933	617,378	455,093	832,309	933,730
Other than stainless	6,908,298	7,863,736	5,442,476	7,737,796	9,190,857
Total	7,428,231	8,481,114	5,897,569	8,570,105	10,124,587
Shipments of steel products:					
For domestic consumption	58,850,458	62,728,250	54,586,039	69,665,819	76,164,539
For export	4,206,692	3,244,888	3,517,971	2,566,473	2,764,411
Total	63,057,150	65,973,138	58,104,010	72,232,292	78,928,950

[1] Revised figure.
[2] American Iron and Steel Institute.
[3] Included in production of ingots and castings.

[1] Proportions are based on shipments for which consuming industry was reported; these shipments were somewhat less than those shown in table 1.

Digitized by Google

According to data compiled by the Bureau of Labor Statistics each employee in the steel industry averaged 41.1 hours of work weekly compared with 39.9 in 1950 and 37.9 hours in 1949. Average hourly earnings per worker were $1.885 compared with $1.689 in 1950 and $1.703 in 1949. There was a gradual increase in employment during 1951, beginning with 559,000 in January and ending with 573,000 in December. The composite price of finished steel, as published by the Iron Age (4.131 cents per pound) remained the same throughout 1951, the last increase being in December 1950.

GOVERNMENT REGULATIONS

The first materials control order (the M order series of NPA) was M–1–Steel, issued October 12, 1950, by the National Production Authority. This order established the general rules for the acceptance and delivery of priority-rated orders received by the producers of the different types of steel, such as bars, pipe, plates, rail, and tin plate. It governed the distribution of steel, except in several special fields, until the Controlled Materials Plan regulations were issued in May and June 1951 to be effective for the third quarter 1951. M–1 was amended numerous times to take care of special programs, such as the freight-car program, and further to define the different steel products controlled by its provisions.

On November 8, 1950, NPA issued M–6 (later M–6A), Steel Distributors, which established the rules for the distribution of the various steel products to steel warehouses and also the distribution of these products by the steel warehouses. The regulation was needed to insure a steady flow of material to these warehouses, so that the small users who bought less than mill quantities could be assured of a continued supply through normal channels.

Owing to a serious shortage of steel scrap which developed in the latter part of 1950, NPA found it necessary on January 4, 1951, to issue M–20, Iron and Steel Scrap. This order, as originally issued, established a 60-day inventory limitation on steel scrap. Later, it was amended to permit the NPA to direct the shipment of scrap held by scrap dealers to selected users. The regulation also contained certain technical provisions, such as segregation of different types of scrap.

On March 7, 1951, NPA issued M–47 (later M–47–A and M–47–B), Use of Iron and Steel. This regulation limited the use of these materials in the consumers' durable goods field to a percentage of a base-period use.

With the advent of the Controlled Materials Plan in the second quarter of 1951, the distribution of steel, along with copper and aluminum, was made subject to its regulations. When in full operation, this plan called for filing applications for steel, both for production and construction, by all users except for certain small-user exemptions. Certain other orders were issued, such as M–80 and its schedules on Alloying Materials and Alloy Products, which affected the distribution, use, and inventories of steel. Another type of action should be mentioned. NPA from time to time issued production directives to the mills to produce certain quantities of certain items of steel in short supply and also required the mills to set aside certain percentages of their production for direct defense and AEC orders.

Digitized by Google

In addition to the orders described above, numerous orders were issued to take care of special problems with regard to use of steel in certain industries such as mining, petroleum, transportation, and power.

PRODUCTION AND SHIPMENTS OF PIG IRON

Domestic production of pig iron, exclusive of ferro-alloys, was 70.3 million net tons in 1951, 9 percent greater than in 1950 and 32 percent more than in 1949. Pig-iron production in 1951 consumed 97.3 million net tons of domestic iron and manganiferous ores and 6.5 million tons of foreign ores, with 62 percent coming from Chile and Sweden; about 0.5 million tons of iron ore was received from Venezuela, a new source for the United States. Blast furnaces consumed 23.5 million tons of sinter and 10.2 million tons of miscellaneous iron-bearing materials. In addition to the above raw materials, 1,997,054 tons of home scrap and 505,331 tons of flue dust were used.

Shipments of pig iron were 70.3 million tons in 1951, 9 percent over 1950 and 33 percent over 1949.

The figures in table 4 cover total shipments, which consist predominantly of molten pig iron transferred to steel furnaces on the site. Values for merchant pig iron are included. However, the average value per ton of pig iron is lower than market prices published in trade journals because handling charges, selling commissions, freight costs, and other related costs are not included. The term "shipped," as distinguished from "production," refers, in the case of on-site transfers, to departmental transfers, upon which value is placed for bookkeeping purposes rather than to actual sales, as in the case of merchant pig iron.

TABLE 2.—Pig iron produced and shipped in the United States, 1950–51, by States

[1] Includes pig iron transferred directly to steel furnaces at same site.

Metalliferous Materials Used.—The production of pig iron in 1951 required 127,285,286 net tons of iron ore, sinter, and manganiferous iron ore; 3,723,803 net tons of mill cinder and roll scale; 3,697,161 net tons of open-hearth and Bessemer slags; 2,681,466 tons of purchased scrap; and 113,825 tons of other materials—an average of 1.957 tons of metalliferous materials (exclusive of home scrap and flue dust) per ton of pig iron made.

Alabama furnaces used red hematite from the Birmingham district and brown ores from Alabama and Georgia, as well as hematite from Missouri and the Lake Superior region. Foreign iron ore from Africa, Brazil, and Sweden, and foreign manganese-bearing ores from Africa, Brazil, Cuba, and India were also used.

Most of the iron ore used at Sparrows Point, Md., was of foreign origin. The sources were Africa, Chile, Cuba, Sweden, and Venezuela; manganiferous ores were received from Africa.

Republic Steel Corp., at Troy, N. Y., received manganiferous ores from South Africa and iron ores from the Adirondack district.

Digitized by Google

Colorado Fuel and Iron Corp. (E. & G. Brooke Iron Division), Birdsboro, Pa., used iron ore and manganiferous ore from Africa and iron ore from New Jersey.

Texas blast furnaces used domestic ore from various sources and foreign ores from Mexico and Brazil. Manganiferous ores from Mexico and India were also used.

Utah furnaces used iron ore from Iron County, Utah, and manganiferous ore from Nevada and Utah.

Kaiser Steel Corp., Fontana, Calif., used iron ore from Eagle Mountain, Riverside County, Calif.

Pueblo, Colo., furnaces (Colorado Fuel & Iron Corp.) used iron ore from Wyoming and Utah and iron and manganiferous ores from New Mexico.

PRODUCTION OF STEEL [2]

Steel production rose to 105.2 million net tons in 1951, an increase of 9 percent over 1950 and 35 percent over 1949. Rated capacity as of January 1, 1951, was 5 percent over 1950 and 8 percent over 1949. The 4.4 million-net-ton-capacity increase during 1951 plus the many improvements in steelmaking practice put into effect by steel companies permitted production to exceed rated capacity for the first time.

In 1950 and 1951, about 89 percent of domestic steel was made in open-hearth furnaces compared with 90 percent in 1949. Seven percent of total steel production in 1951, 6 percent in 1950, and 5 percent in 1949 was in electric furnaces.

TABLE 7.—Steel capacity, production, and percent of operations in the United States, 1947–51, in net tons [1]

[American Iron and Steel Institute]

Year	Annual capacity as of Jan. 1	Production					
		Open-hearth	Bessemer	Crucible	Electric	Total	Percent of capacity
1947	91,241,250	76,873,793	4,232,543	18	3,787,717	84,894,071	93.0

Total	76,873,793	79,340,157	70,248,803	86,262,509	93,166,518

[1] Includes only that portion of steel for castings produced in foundries operated by companies manufacturing steel ingots. *See* table 7.

Alloy Steel.—Alloy-steel output for 1951 was 10,125,000 net tons, the highest production for alloy steel since 1944. The production increase for 1951 was 18 percent over 1950 and 72 percent over 1949. Alloy production represented 10 percent of the total steel made in 1951, 9 percent in 1950, and 8 percent in 1949. Of the alloy steel produced in 1951, 65 percent was produced in basic open-hearth, 2 percent in the acid open-hearth, and 33 percent in electric furnaces.

[2] The data concerning steel production used by the Bureau of Mines are furnished by the American Iron and Steel Institute. The output from steel foundries that do not produce steel ingots is not included in the production data.

Digitized by Google

These figures reflected an increase in the proportions produced by electric furnaces (32 percent in 1950) and acid open-hearth furnaces (1 percent in 1950). Alloy-steel data include steels in which the minimum of the range specified in one or more of the elements named exceeds the following percentages: Manganese, 1.65 percent; silicon, 0.60 percent; copper, 0.60 percent; or aluminum, boron, chromium, cobalt, columbium, molybdenum, nickel, titanium, tungsten, vanadium, zirconium and other alloying elements, any added percent.

Metalliferous Materials Used.—During 1951 steel furnaces used 3.8 million tons of domestic iron ore and 2.4 million tons of foreign ore; the latter originated in Africa, Brazil, Canada, Cuba, Sweden, and Venezuela. Also used was 1.7 million tons of sinter made from both foreign and domestic ores.

Digitized by Google

Scrap and pig iron used in steel furnaces in 1951 totaled 118.8 million net tons. The percentage of each used (48 and 52 percent, respectively) was the same as in 1950. The basic open hearth makes use of both charge and feed ores. Charge ore is added to furnish available oxygen to the charge before the heat is melted. The properties that are acceptable in charge ore or sinter vary with furnace size, hot-metal analysis, and amount of ore used. The sum of the acid compounds, SiO_2 plus Al_2O_3 plus TiO_2 should be under 8 percent. Up to about 8 percent natural moisture in the charge can be tolerated in most practices. With the present trend in industry to use higher sulfur fuels in the open hearth, the sulfur content of the ore should be below 0.05 percent.

Feed ore is used after a heat is melted to accelerate the oxidation of carbon during the refining period. The physical and chemical characteristics desired in charge and feed ore are very similar. Both ores should be hard and dense and free from fines. Mill cinder, sinter, and roll scale may be used in place of feed ore, but none is as effective for carbon removal as ore. Roll scale is sometimes used in conjunction with spar during the working of heats that are high in phosphorus. Owing to limited domestic supply of charge and feed ore, substantial amounts of these ores are now obtained from foreign sources (in 1951, about two-fifths of the total of such ores used in steel furnaces), mainly from South America and Africa.

TABLE 12.—Metalliferous materials consumed in steel furnaces in the United States, 1947–51, in net tons

	Iron ore		Sinter	Manganese ore		Pig iron	Ferro-alloys	Iron and steel scrap

CONSUMPTION OF PIG IRON

Consumption of pig iron in 1951 increased 10 percent over 1950 and 34 percent over 1949. Of the total pig iron, 78 percent was consumed in 8 Middle Atlantic and East North Central States as shown in table 14. In 1951, 86 percent of the pig iron went to the steelmaking furnaces to be processed into steel; 4 percent was used to make direct castings and 10 percent to iron furnaces. These percentages were the same as in 1950.

There were plants using pig iron in 1950 in all 48 States and the District of Columbia; Pennsylvania, Ohio, and Indiana consumed 59 percent of the total.

[1] Consumption for 1951 obtained from sample monthly canvasses; therefore, exact number of consumers by States not available.
[2] In 1947 some pig iron consumed in California, Illinois, Kentucky, Maryland, New Jersey, Ohio, and Pennsylvania—not separable—is included with "Undistributed."

PRICES

The average value of all grades of pig iron given in table 15 was compiled from producers' reports to the Bureau of Mines. The figures represent value f. o. b. blast furnaces and do not include the value of ferroalloys. The annual average value for all grades of pig iron at furnaces was $46.75 in 1951 compared with $42.85 in 1950.

The average monthly prices of foundry, Bessemer, and basic pig iron at Mahoning Valley furnaces and foundry pig at Birmingham furnaces, according to published market quotations, are summarized in table 16.

FOREIGN TRADE [3]

Imports and exports of steel both increased in 1951, while pig-iron exports decreased and imports increased. Imports of steel (manufactures and semimanufactures) rose from 1,099,000 tons (revised) in 1950 to 2,289,000 tons in 1951, and exports increased 14 percent. Pig-iron imports increased from 805,000 tons (revised) in 1950 to 1,067,000 in 1951, while exports decreased from 6,813 tons ($321,795) to 6,555 tons ($352,353).

Sixty-nine percent of the pig iron imported came from Austria, Canada, Germany, and the Netherlands, while Australia, Canada, and Mexico received 95 percent of the exported tonnage.

[1] Revised figure.

Steel bars, boiler and other iron and steel plate, and structural iron and steel were principal imports. Sheets (black and galvanized), tinplate and terneplate, casing and line pipe, structural shapes, and rails made up 60 percent of the exports.

[3] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

WORLD PRODUCTION

World production of steel and pig iron (including ferroalloys) increased 12 percent each in 1951 over 1950. These materials had increased 18 and 16 percent, respectively, in 1950 over 1949. In 1951, the United States was first and Russia second in both pig iron and steel production, West Germany attained third place in pig-iron output, and the United Kingdom was third in steel production.

Austria.—Pig-iron, crude-steel, and rolled-steel output attained alltime highs in 1951, with production at 270, 158 and 151 percent, respectively, of prewar (1937) levels. Compared with 1950, crude steel increased 9 percent while pig iron and rolled steel increased 19 percent each. At Voest, a third blast furnace was blown in during May 1951, and a new slabbing mill, a European Recovery Program project, began operation in August. This mill can produce 300,000 tons of slabs per year on a two-shift basis.[4]

Burma.—Burma was planning to construct a State-owned rolling mill, which was scheduled to melt and roll 5,000 tons of scrap iron and steel a year. An estimated 50,000 tons of scrap was available in the country.[5]

India.—India produced over 1.5 million tons of steel in 1951. Construction of a 500,000-ton steel plant in the State of Madhya Bharat was being reconsidered.

Mexico.—A $5 million expansion of the Altos Hornos steel mill at Monclova, Coah., was expected to get underway soon, increasing the finishing capacity of the plant from 115,000 to 185,000 tons annually.[6]

Philippines.—Orders for equipment for the country's first steel mill at the Marcelo plant in Manila, which will consist of three electric furnaces, a rolling mill and a fire-brick plant had been placed, and operation was expected to begin in 1952.

Output from full production reportedly was expected to reach 44,000 tons of steel ingots.[7]

Spain.—Total steel production in 1951 was 831,000 metric tons, a 3-percent increase over the 807,000 tons produced in 1950. During the last half of the year increased supplies of local scrap (though of poor quality) and increased imports of coke, combined with ample electric power, enabled the steel industry to reach a new postwar high. Sociedad Metalurgia Duro Felguera, La Felguera, Oviedo Province, started operating several Bessemer-type converters and a new electric furnace that raised the company capacity by 57,000 tons annually. It was the only steel company in Spain to show a sizable gain in steel production—about 30 percent. The scrap requirements of this company were expected to be reduced considerably by the newly installed duplex process.[8]

U. S. S. R.—The Soviet Union produced over 31 million metric tons of steel in 1951, exceeding the production of the United Kingdom and Germany combined. This put the Soviet Union well into second place in world steel production.

United Kingdom.—The British iron and steel industry went under Government control February 15, 1951. Steven Hardie was made chairman of the new organization, the Iron & Steel Corp., which is composed of 180 firms that cost the Government £230 million. He stated that the new capital plans for the industry involve spending £500 million during the next 5 years.

British steel production declined slightly in 1951 from the 1950 record high of 16,554,000 tons, while there was a slight increase in pig-iron production. The principal cause for the decreased steel production was the shortage of scrap and other raw materials. According to the British Iron and Steel Federation, steel production could have reached the original estimate of 16 million tons in 1951

had the iron foundries not been allowed to use more scrap and pig iron in 1951 than they did in 1950. This diversion of scrap and pig iron caused a greater shortage of these materials at steel-making furnaces.[9]

Iron and Steel Scrap

By James E. Larkin

GENERAL SUMMARY

THE QUANTITY of ferrous materials (scrap and pig iron) consumed in 1951 was the largest in history, totaling 148.1 million short tons to exceed the previous record year (1950) by 11 percent. In 1951, 38.8 million short tons was home scrap, and 37.9 million tons was purchased scrap, each establishing a record year, making a total of 76.7 million tons, which represented 52 percent of the total charge. Home scrap was consumed in 1951 at an average monthly rate of 3,238,000 short tons; March (3,457,326 tons), was the largest month on record, and January, April, May, and October were also all greater than the previous record month of October 1950. Purchased-scrap consumption in 1951 was at a record monthly rate of 3,156,000 short tons. The record purchased-scrap consumption was also in March (3,472,697 short tons), and January, April, May, June, August, and October were all greater than the previous record month—October 1950. Purchased-scrap consumption for the year exceeded 1950 by 4.5 million short tons; 1948, the greatest peacetime year, by 5.3 million tons; and 1942, the highest wartime year, by 10.7 million tons. The large use of ferrous scrap resulted in a greater demand for pig iron; accordingly, a record year was established by the use of 71.4 million short tons. Consumption of pig iron in October (6,273,559 tons) was the greatest quantity used in any one month, and the total for the year exceeded the previous year by 6.5 million short tons, or 10 percent.

The proportions of scrap and pig iron used in steel furnaces in 1951—the same as in 1950—were 48 and 52 percent, respectively, compared with 47 and 53 percent in 1949. The charge of scrap and pig iron used in iron foundries, mainly cupola furnaces, comprised 65 percent scrap and 35 percent pig iron, the same as in 1950 and 1949.

The increased consumption of purchased iron and steel scrap reduced stocks of this material held by consumers to a level 20 percent lower on December 31 than at the beginning of the year—equivalent to a 31-day supply at the 1951 average daily consumption rate of 103,474 short tons. Stocks reached a high of 4,125,351 short tons for the year at the end of January but decreased steadily to a low of 2,941,465 short tons at the end of June. In order to alleviate the purchased-scrap shortage, which was caused by the mills expanding their production facilities to meet the requirements of an increased military program as well as domestic needs, the Government, through the National Production Authority, organized committees in industry to appoint representatives in their organizations to urge the collection of all dormant plant scrap and to identify machinery that was obsolete and could be scrapped. Federal Government agencies, including the

Digitized by Google

Navy and Army, Maritime Commission, and the Interior and Agriculture Departments, were called upon to urge their various installations, yards, mines, and experiment stations to turn in all possible scrap. Results of this combined effort on the part of the scrap iron and steel industries and Government agencies to bring out as much scrap as possible were evident by the end of October, when the stocks of purchased scrap held by consumers had advanced to more than a 30-day supply.

TABLE 1.—Salient statistics of ferrous scrap and pig iron in the United States, 1950–51

	1950 (short tons)	1951 (short tons)	Percent of change from 1950
Stocks, December 31: Ferrous scrap and pig iron at consumers' plants:			
Home scrap	1,469,463	1,198,556	−18
Purchased scrap	3,950,863	3,167,501	−20
Pig iron	1,800,137	1,750,986	−3
Total	7,220,463	6,117,043	−15
Consumption: Ferrous scrap and pig iron charged to—			
Steel furnaces: [1]			
Home scrap	27,353,503	30,100,917	+10
Purchased scrap	23,738,078	26,986,412	+14

GOVERNMENT REGULATIONS

Regardless of the above-mentioned efforts to bring out more scrap and build up consumers' inventories to a safe level, it was decided that some means of control over stocks and prices was necessary.

National Production Authority Regulation 1, effective September 18, 1950, had provided for a measure of control over inventories of commodities in short supply, including iron and steel scrap. However, this merely restricted commercial dealers to "a practicable minimum working inventory." Order M–20, on the other hand, effective January 4, 1951, amplified Regulation 1, with respect to iron and steel scrap, by prohibiting any regular dealer, broker, automobile wrecker, or producer of scrap from receiving in any 60-day period (except for certain normal seasonal operations) iron and steel scrap that would increase his inventory position beyond either a minimum practicable working inventory or beyond his average inventory position during the preceding 60-day period, whichever was the lesser. This order, in turn, was amended, effective January 29, 1951, to provide that NPA might (1) establish limitations on consumers' scrap inventories and (2) allocate scrap and specifically direct the manner and quantities in which deliveries were to be made. March was the first month of allocation of scrap from dealers to consumers. Special controls over automobile wreckers were established on December 11, when NPA issued Order M–92, requiring an inventory report from automobile wreckers by December 20, covering the number of motor vehicles, car units,[1] and poundage of loose scrap. The order put a ceiling on acceptance by automobile wreckers of delivery of motor vehicles and car units and required a quarterly turnover both of car units and of motor vehicles manufactured before 1946. It also required automobile wreckers to comply with National Production Authority allocation directives at any time.

Prices of iron and steel scrap were covered by the general price freeze imposed by the Office of Price Stabilization on January 26, 1951, and subsequently were brought under specific control by Ceiling Price Regulation 5 of February 5.

CONSUMPTION

The use of scrap and pig iron increased in every district[2] during 1951, the total being 11 percent greater than in 1950. There was a noticeably greater amount of scrap than pig iron used in the New England, West North Central, West South Central, and Pacific districts. These districts together used 11 percent of the total scrap consumed in 1951 and 4 percent of the pig iron, compared with 10 and 4 percent, respectively, in 1950. The average ratio of scrap to pig

[1] A car unit was defined as any motor vehicle, regardless of age, stripped of salvageable parts or 1,500 pounds of loose scrap, that is, detached nonsalvageable material resulting from dismantling operations.
[2] The geographical districts have been rearranged in this chapter to be the same as the geographical divisions used by the Bureau of the Census.

Digitized by Google

iron in these four districts combined was 2.6:1, whereas the United States average was 1.07:1. Owing in part to the type of operations in these four districts the scrap to pig-iron ratio varies somewhat from the United States ratio. The United States as a whole used 7 percent more scrap than pig iron in 1951 compared with 6 percent in 1950.

Open-hearth furnaces continued to be the largest consumers of ferrous scrap and pig iron, increasing their consumption over that of 1950 by 3.9 million tons of scrap and 5.1 million tons of pig iron. Open-hearth consumption took 62 percent of the total scrap in 1951 and 63 percent in 1950, comprised of 68 percent of the home scrap in 1951 (the same as in 1950) and 55 percent of the purchased scrap in 1951 (58 percent in 1950). Pig-iron consumption in open hearths accounted for 78 percent of the total pig iron consumed (the same as in 1950).

Cupola-furnace consumption in 1951 was as follows: Home scrap, 15 percent of the total home scrap consumed (the same as in 1950); purchased scrap, 17 percent (compared with 16 percent in 1950); pig iron, 9 percent (the same as for the 4 years preceding 1951).

Bessemer converters consumed 8 percent of the pig iron during 1951 (the same as in 1950), compared with 9 percent in 1949, and 0.4 percent of scrap (the same as for 1950 and 1949).

Electric furnaces consumed 12 percent of the total scrap (1 percent more than in 1950 and 3 percent more than in 1949) and 0.2 percent of the pig iron (unchanged from 1949–50).

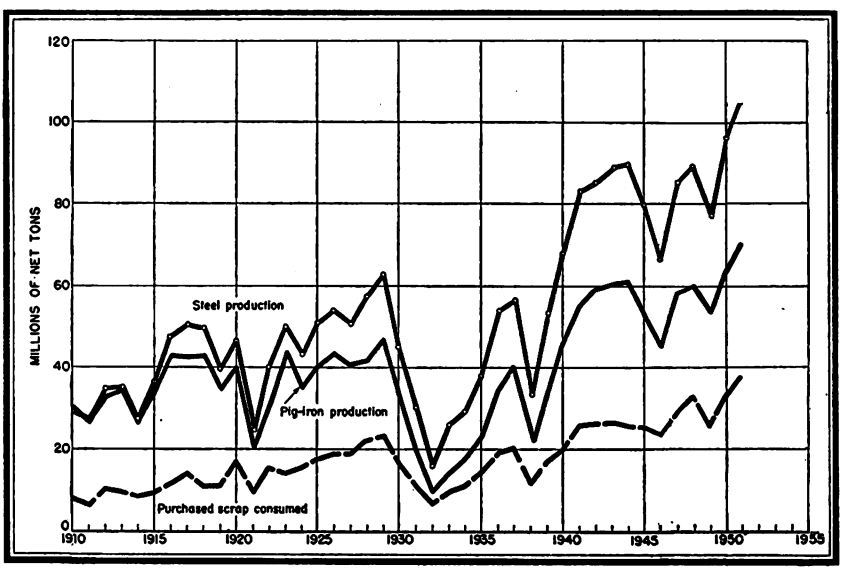

FIGURE 1.—Consumption of purchased scrap and output of pig iron and steel in the United States, 1910–51. Figures on consumption of purchased scrap for 1910–32 are from State of Minnesota vs. Oliver Iron Mining Co., et al., Exhibits, vol. 5, 1935, p. 328; those for 1933–34 are estimated by authors; and those for 1935–51 are based on Bureau of Mines records. Data on steel output are from the American Iron and Steel Institute.

CONSUMPTION BY DISTRICTS AND STATES

During 1951 iron and steel scrap and pig iron were used in all 48 States and the District of Columbia. The largest consuming districts were East North Central, Middle Atlantic, and South Atlantic. (*See* table 6). All districts increased over 1950 in total scrap and pig-iron consumption. The States having the largest consumption of scrap, with the percentage consumed, were: Pennsylvania 24, Ohio 18, Illinois 10, and Indiana 9.

Consumption for 1951 was obtained from sample monthly canvasses; therefore, exact number of active plants by States is not available.

CONSUMPTION BY TYPE OF FURNACE

Open-Hearth Furnaces.—Ferrous scrap and pig-iron consumption in open-hearth furnaces in 1951 totaled 103.5 million short tons, an increase of 10 percent over 1950, and established a record high consumption of these materials by this type of furnace. The use of home scrap increased 9 percent over 1950 and was 2 percent greater than in 1944, the previous record year for the use of this material. Purchased scrap increased 8 percent, total scrap 9 percent, and pig iron 10 percent. The open-hearth furnace melt in 1951 consisted of 46 percent scrap and 54 percent pig iron (unchanged from 1950). Of the total scrap consumed, 44 percent was purchased (the same as in 1950) compared with 42 percent in 1949.

Pennsylvania continued to be the leading State in the use of scrap in the open hearth, followed by Ohio, Indiana and Illinois; this rank has remained unchanged since 1936.

Bessemer Converters.—The 5.9 million short tons of ferrous raw materials used in Bessemer converters in 1951 represents an 8-percent increase over the 1950 use of these materials. The ratio of scrap to

Digitized by Google

total metal charge was 1:20 compared with 1:21 during 1950; of the scrap used, 85 percent was home scrap, slightly higher than the previous year.

Following the usual pattern, Pennsylvania was the principal consumer of converter scrap in 1951. Ohio was the largest consumer of pig iron in this type of furnace, using 44 percent of the total.

Although the use of ferrous raw materials, was greater in 1951 than 1950, it was less than in the years 1941 through 1944, with 1943 the record year for the consumption of these materials in Bessemer converters.

Electric Steel Furnaces.—The melt of ferrous scrap and pig iron used in electric furnaces in 1951 represented an all-time record for the use of these materials in this type of furnace. The melt totaled 9.5 million short tons, an increase of 27 percent over the 7.5 million tons used in 1950, the previous record year. Of the total scrap used, 6.1 million tons was purchased scrap, a new record for the use of this material in electric furnaces. Increases in the use of scrap occurred in all districts; pig iron decreased in the East North Central, West North Central, and Pacific districts.

Cupolas.—Figures released by the Bureau of the Census, United States Department of Commerce, indicate that shipments of gray-iron castings in 1951 increased 9 percent over 1950. Accordingly, requirements for scrap and pig-iron cupola consumption increased in 1951, which resulted in a new record high being attained in the use of these materials in this type of furnace. These furnaces used 18.9 million short tons of scrap and pig iron, a 13-percent increase over the 16.8 million tons used in 1950, the previous record year. The use of home scrap increased 9 percent, purchased scrap 21 percent, total scrap 15 percent, and pig iron 8 percent.

Charges to cupolas consisted of 31 percent home scrap, 34 percent purchased scrap, and 35 percent pig iron compared with 32, 32, and 36 percent, respectively, in 1950.

Michigan continued to be the largest consumer of cupola scrap, followed in order by Ohio, Illinois, and Pennsylvania.

Air Furnaces.—Scrap and pig iron consumed in air furnaces (including 2 Brackelsbergs) in 1951 amounted to 1.8 million short tons (an increase of 20 percent over the 1.5 million tons melted in these furnaces in 1950). The use of home scrap, purchased scrap, and pig iron each increased by 20 percent over 1950. The total charge of iron and steel scrap and pig iron in air furnaces during 1951 was comprised of 49

percent home scrap, 29 percent purchased scrap, and 22 percent pig iron (the same as in 1950).

Ohio led in the use of scrap in air furnaces, followed in order by Illinois and Pennsylvania. (*See* table 12).

Crucible and Puddling Furnaces.—Crucible furnaces used 172 short tons of scrap and 243 tons of pig iron in 1951 compared with 926 and 1,190 tons, respectively, in 1950. There was no tonnage of iron and steel scrap reported as being melted in puddling furnaces during 1951.

Blast Furnaces.—Materials other than scrap constitute by far the largest proportion of the blast-furnace charge and in 1951 consisted of 127,285,286 short tons of iron ore, sinter, and manganiferous ore; 3,723,803 tons of mill cinder and roll scale; 3,697,161 tons of open-hearth and Bessemer slag; and 113,825 tons of miscellaneous materials.

Total consumption of scrap in blast furnaces during 1951 was 4.5 million short tons, a 2 percent increase over 1950. The scrap charged

[1] Includes 2 Brackelsberg furnaces, 1 each in Indiana and Ohio.

to blast furnaces was 45 percent home, 55 percent purchased, compared with 46 and 54 percent, respectively, in 1950 and 50 percent, respectively, in 1949. The proportion of scrap used to pig iron produced was 6.4 percent, comprised of 2.9 percent home scrap and 3.5 percent purchased scrap, compared with 6.8 percent in 1950. (*See* table 13).

USE OF SCRAP IN FERROALLOY PRODUCTION

The producers of ferroalloys (by other than blast furnaces) in 1951 consumed 414,949 short tons of scrap, a 17 percent increase over 1950. Of this total, 405 tons was used in the aluminothermic process and the balance in electric furnaces. Purchased scrap represented 97 percent of the quantity used and home scrap, 3 percent; in 1950 these percentages were 96 and 4, respectively. (*See* table 14).

Digitized by Google

Nineteen ferroalloy plants used ferrous scrap in 1951. All of these plants operated electric furnaces. Two of this group employed both the electric and aluminothermic process.

Scrap used in blast furnaces in the manufacture of ferroalloys is included in this chapter with blast furnaces.

MISCELLANEOUS USES

Scrap consumed in 1951 for miscellaneous purposes, such as re-rolling, nonferrous metallurgy, and as a chemical agent, amounted to 1.3 percent of the total consumption. This was the first time in 7 years that it had not been almost 2 percent. The quantity so used—997,558 short tons—was a decrease of 13 percent from that used for these purposes in 1950. Of the quantity used, 96 percent was purchased scrap and 4 percent home scrap.

STOCKS

Complete iron-and steel-scrap stock figures covering 1951 year-end stocks are not available; producers (railroads and manufacturers) were not canvassed. Dealers, automobile wreckers, shipbreakers and consumers reporting to the Bureau of Mines had 5.5 million short tons of material on hand December 31, 1951, compared with 5.7 million tons at the end of 1950—a decrease of 261,519 tons or 5 percent.

Consumers' Stocks.—Consumers' stocks of home and purchased iron and steel scrap on December 31, 1951, totaled 4.4 million short tons—a decrease of 1.1 million tons or 19 percent from the beginning of the year. Stocks of home scrap (1.2 million tons) decreased 18 percent and purchased scrap (3.2 million tons) 20 percent. Stocks of pig iron on December 31, 1951, totaled 1,750,986 short tons—a decrease of 3 percent from the 1,800,137 tons on hand December 31, 1950.

Suppliers' Stocks.—Stocks of iron and steel scrap in the hands of a combined total of 1,989 dealers, automobile wreckers, and shipbreakers as reported to the Bureau of Mines totaled 1.1 million short tons on December 31, 1951.

PRICES

The price of No. 1 Heavy-Melting scrap at Pittsburgh as reported in the January 2, 1951, weekly issue of Iron Age was $46.13 compared with $29.75 per gross ton at the same time for the previous year and by the end of the month had advanced to $51.13 compared with $30.75 at the end of January 1950. This price prevailed until February 5, when it was rolled back to $44 per ton by the Office of Price Stabilization, a level $24 per ton over the ceiling placed on No. 1 Heavy-Melting and Cast scrap by the Office of Price Administration during World War II. Cast scrap on Jan. 2, 1951, was quoted at $67.75,

Digitized by Google

compared with $37.50 at the same time in 1950. At the same time that other prices of scrap were rolled back, a ceiling of $49 per gross ton was placed on cast-iron scrap.

The composite price of iron and steel scrap, as reported in the Iron Age Annual Review, was $46.15 per gross ton in January 1951, a new record high and an increase of $19.57 over the $26.58 per gross ton quoted at the same time for 1950. With price regulations effective in the early part of the year, the composite price of iron and steel scrap dropped to $43 in March; this price prevailed until October, when it decreased to $42.50 per gross ton for the 1 month, then declined to $42 for November and December 1951. The No. 1 Cast scrap composite price at Chicago was $63 per gross ton in January, an increase of $24.50 per ton over January 1950 but $11.30 below the peak price of $74.30 per gross ton in August 1948. No. 1 Heavy-Melting at Pittsburgh and Chicago was quoted in Iron Age Annual Review at a price of $47.13 and $44.63, respectively, in January 1951, high for the year, but decreased to a low of $43 and $41.50 per gross ton, respectively, in November and December. The prices set by the Office of Price Stabilization for No. 1 Heavy-Melting steel at Pittsburgh and Chicago, respectively, were $44 and $42.50 per gross ton.

FOREIGN TRADE [3]

Imports.—Imports of iron and steel scrap, including tin-plate scrap, totaled 416,858 short tons in 1951, a decrease of 47 percent from the 785,230 (revised) short tons imported in 1950, with the value amounting to $15,009,285 compared with $18,718,895 (revised) in 1950, a decrease of 20 percent. The decline in imports during 1951 was due in part to a decrease in scrap collections and the increased requirements in the countries that had been the principal suppliers during the past few years. Of the 1951 imports, 69,799 tons came from Canada, 63,912 from Germany, 43,870 from Cuba, 31,648 from Japan, 27,844 from France, and the remainder from other countries. There was 57,759 tons of tin-plate scrap imported in 1951, mostly from Canada, compared with 47,481 in 1950.

Exports.—Exports of ferrous scrap from the United States in 1951 were 245,340 short tons valued at $9,094,473, a 13-percent increase in tonnage over 1950 and a 51-percent increase in value. Imports exceeded exports by 171,518 short tons. The tonnage exported amounted to 7 percent of the 5-year prewar average (1935–39) of 3.3 million tons a year, the same percentage as in 1950. The 1951 exports included 15,622 tons of tin-plate scrap, tin-plate circles, strips, cobbles, and terneplate clippings and scrap valued at $2,279,258. The same materials in 1950 amounted to 8,609 (revised) tons valued at $758,972 (revised).

[3] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

WORLD REVIEW

Hong Kong.[4]—Chinese interests in Hong Kong scoured the ports of the world for second-hand ships which they broke up either as scrap or reprocessed steel for sale to the Chinese Communists. At the same time, these interests purchased large quantities of scrap abroad for delivery to China. China's demand was so keen that dealers paid very high prices for old hulks that would barely float. Purchases were made in such diverse regions as France, India, and New Zealand.

The cost of scrap iron in Hong Kong in February 1951 was about 400 Hong Kong dollars compared with 60 to 110 in 1948, depending on whether the ship was sunk or afloat.

Annual trade figures reflected the enormous increase in Hong Kong's exports of iron and steel. The value of these exports rose from 37.7 million Hong Kong dollars in 1949 to 124 million in 1950.

Most of the secondhand ships were broken up by Chinese companies in Hong Kong, where a certain amount of reprocessing was also done. Some of this scrap or reprocessed steel was devoted to Hong Kong's own needs, but it was estimated that at least 75 percent was being reexported to China. Companies in China were also busy breaking up ships. At least six tankers and freighters that had been laid up in Hong Kong waters since the war were towed to Whampoa (near Canton) for this purpose during December 1950 and January 1951. All this scrap and reprocessed steel was sent by railway from Canton to Chinese mills in the north.

Digitized by Google

Netherlands.[5]—Shortage of scrap in the Netherlands resulted in the shutting down of one of the five open-hearth furnaces at the Koninklijke Hoogovens en Stallfabrieken at Ymuiden. The company involved could not pay ruling prices for scrap because it was obliged to sell steel at or below a fixed ceiling price. Coke supplies also caused it some concern.

Sweden.[6]—The future supply of scrap was not expected to be quite as promising as that of Swedish iron ore. The importance of scrap as a raw material in the manufacture of steel has been steadily increasing. In June 1951 about a quarter of all the steel produced in Sweden was derived from scrap. The Swedish steelworks consumption of purchased scrap usually amounts to about 400,000 metric tons a year. Barely half of their requirements can usually be met out of domestic sources, while the rest (about 180,000 tons) has to be imported. During the early postwar years it was comparatively easy to procure scrap from abroad; but in recent years it has become increasingly difficult, and since the outbreak of the war in Korea there has been an ever-growing shortage of scrap. The principal supplier of scrap to Sweden after World War II was Western Germany. By 1951 the steel production in Western Germany increased and seriously limited German scrap exports. Sweden's imports of German scrap were estimated to amount in 1951 to not more than 125,000 tons.

United Kingdom.[7]—A sharp drop in collections of scrap iron and steel in Germany imperiled exports of scrap to the United Kingdom and to the United States. Talks took place between the United Kingdom and United States high commissioners and the German Federal Chancellor to arrive at some satisfactory solution to this situation. An agreement, signed in September 1951, was based upon a normal collection of 450,000 short tons of scrap per month. German industry was guaranteed the first 325,000 tons, with the United States and the United Kingdom assured of at least 62,000 tons each a month. However, the first month's collection after the agreement came to only 344,000 tons, leaving for export to the United States and the United Kingdom combined some 19,000 tons, as against shipments of 128,000 tons in the same month in 1950.

Lead[1]

By O. M. Bishop and Edith E. den Hartog

GENERAL SUMMARY

THE LEAD INDUSTRY in 1951 was characterized by a marked decrease in imports, lessened mine output, and the greatest recovery of secondary lead on record. Although consumption was 4 percent less than in 1950, new supplies were inadequate, and lead was withdrawn from the stocks of consumers, producers, and Government to meet the demand. A ceiling price of 17.00 cents per pound, New York, was established January 26 on domestic lead, and selling prices were generally quoted at the ceiling until October 2 when the Office of Price Stabilization authorized an increase of 2 cents a pound. The increase became effective immediately and remained to the end of the year. Before October 2 domestic consumers could buy lead abroad at any price, but after that date regulations prevented the purchase of foreign lead at prices over the domestic ceiling price plus duty. Unable to sell all of the lead they produced outside of the United States, certain foreign producers were forced to lower their prices, and there was every indication that by early 1952 additional foreign supplies would be available at the ceiling price.

The total supply of 1,155,000 short tons of lead was composed of 388,000 tons of recoverable mine production, 518,000 tons of secondary lead, and imports (excluding scrap) equal to 249,000 tons, lead content. Consumption of lead, including that in pigments and chemicals, totaled 1,185,000 tons. Producers' stocks of refined primary lead declined from 28,894 tons at the beginning of the year to 18,518 tons on December 31, 1951, but antimonial lead stocks remained about the same. Consumers' stocks decreased 37,124 tons during the year to 102,760 tons.

The drop in mine output from 431,000 tons in 1950 to 388,000 tons in 1951 was attributed partly to shutdowns at most lead mines and mills in the Western States from August 23 to September 6. The decrease in producers' stocks was due partly to strikes at the Selby, Omaha, Perth Amboy, Herculaneum, and Bunker Hill plants and to a fire at the Tooele smelter which curtailed production. The decline in imports was attributed almost wholly to the higher prices paid in foreign markets and to the existence of a domestic tariff that added to the cost of foreign metal.

GOVERNMENT REGULATIONS

In 1951 the Government exercised limited controls over the lead industry owing to concern over possible shortages for defense requirements. Lead was brought under inventory control on February 16 through National Production Authority Order M–38. This order was

[1] This report deals primarily with the smelting, refining, and consuming phases of the industry. For details of mining operations, see various State chapters of this volume.

[2] Revised figure.

amended on May 28 to set forth certain limitations on the acceptance of rated orders so as to provide for creation of a set-aside reserve of pig lead to meet emergency conditions and to establish limitations on the use of lead and lead products. Beginning June 1 the amended order restricted the use of lead to not more than 100 percent of the average monthly quantity used during the first 6 months of 1950 and prohibited its use for any new purposes. Order M–76, issued on July 26, placed the supply of soft pig lead produced by primary refiners under allocation control as of September 1 to assure equitable distribution. Effective November 1, imported pig lead was also placed under allocation control by Order M–76 as amended.

DOMESTIC PRODUCTION

Statistics on lead output may be prepared on a mine or smelter and refinery basis. Mine-production data, compiled on the basis of lead content in ores and concentrates, adjusted to account for average losses in smelting, are a better measure of domestic output from year to year and are most accurate for showing the geographic distribution of production. Pig-lead output, as reported by smelters and refiners, presents a more precise figure of actual lead recovery but indicates only in a general way the source of crude material treated. Smelter and refinery output generally differs from the mine figure owing to the lag between mine shipments and smelter treatment of ores and concentrates.

MINE PRODUCTION

Domestic mine output of recoverable lead declined 10 percent in 1951 compared with 1950 and was the lowest annual output since 1947. Production during the first half of the year was at a rate well above the 1,063-ton average daily output for the entire year. In July, August, and September production was considerably below the daily average

Digitized by Google

for the year, while output during the last quarter approximately equaled the average output per day for the year.

Production in 9 of the 16 States producing over 1,000 tons of recoverable lead in 1951 decreased from the 1950 output. Virginia's output was the lowest since the State's production was first recorded separately in 1939. In Arizona, Nevada, and Idaho mine production was the smallest since 1944, 1945, and 1946, respectively. On the other hand, Colorado produced more lead in 1951 than in any year since 1927, and Montana's output was the largest since 1940.

Of the total lead produced in the United States in 1951, 68 percent came from 25 properties. Missouri continued to rank first among the States in the production of lead, and the Southeastern Missouri district continued to be the largest producer of lead, supplying nearly 32 percent of the total domestic output. As in previous years, the St. Joseph Lead Co. produced the bulk of the district's output from its Bonne Terre, Desloge, Federal, and Leadwood mine groups in St. Francois County and, as a joint venture with the National Lead Co., the Mine La Motte property in Madison County. Each mine is equipped with a mill; the 5 have a combined daily capacity of about 28,800 tons of ore. In Madison County the National Lead Co. St. Louis Smelting & Refining Division, operated its Madison lead-copper mine and 1,200-ton flotation mill at Fredericktown throughout the year, except for a 7-week period in April and May when operations were stopped owing to a strike. The St. Joseph Lead Co. began construction of 2 new mills during the year, 1 at Hayden Creek and the other at Indian Creek. The Midwest Mining & Milling Co. acquired the Catherine and Fleming mine, formerly held by the Fredericktown Lead Co., and continued exploration and development work on the property.

Lead production in the Tri-State district declined 14 percent in 1951, chiefly because of the lower grade of ore mined. This decrease occurred despite substantially higher concentrate prices than in 1950 and a 14-percent increase in zinc production. The Eagle-Picher Co., Mining & Smelting Division, was by far the largest producer in the district and was followed by the American Zinc, Lead & Smelting Co., Nellie B. Division. Other large producers were the National Lead Co. St. Louis Smelting & Refining Division, Federal Mining & Smelting Co., and Bilharz Mining Co. In December 1951, 19 mine mills and 3 tailings mills were operating in the district compared to 16 mine mills and 4 tailings mills in 1950.

Mine production of recoverable lead in the combined Western States decreased 10 percent in 1951. During the year mines in these States accounted for nearly 60 percent of the total domestic output or about the same as in 1950.

Idaho continued to be the largest producer of lead in the Western States and second only to Missouri in the United States despite a 23-percent reduction in output in 1951. The decline resulted principally from a shortage of underground miners in late summer and early fall and a 2-week strike of mine, mill, and smelter workers in August and September. In 1951, 92 percent of Idaho's total lead came from the Coeur d'Alene region and most of the remainder from the Warm Springs and Bayhorse districts. The Bunker Hill & Sullivan mine at Kellogg was by far the largest producer. The 5 leading producing

Digitized by Google

mines—the Bunker Hill & Sullivan, Page, Star, Morning, and Triumph—contributed over 59 percent of the State total lead. Other important producers were the Sidney group, Dayrock, Tamarack, Constitution, Sunshine, and the Frisco group properties. Zinc-lead ore and old tailings from the Coeur d'Alene region yielded 78 percent of State output.

Utah increased its output of lead 13 percent in 1951, although the leading properties were idle for about 2 weeks because of strikes. The United States & Lark mine at Bingham was again the principal producer. Other important lead-producing mines were the Chief No. 1, Park Utah Consolidated, Silver King Coalition, New Park, Calumet, Butterfield, Chief Consolidated Tailings, Ophir, and Hidden Treasure. These 10 properties supplied about 96 percent of the State lead. Of the total output nearly 88 percent was recovered from zinc-lead ore and 6 percent from lead ore.

Lead production in Colorado in 1951 increased for the fifth consecutive year and was the largest since 1927. The larger producing mines, in order of rank, were the Resurrection group, Treasury Tunnel-Black Bear (Idarado) group, Eagle, Smuggler Union group, and Shenandoah-Dives group. Zinc-lead ore and zinc-lead-copper ores yielded 69 percent of State total lead, zinc ore 14 percent, gold and silver ores 9 percent, and lead ore 7 percent.

Montana lead production in 1951 increased 9 percent over the 1950 output and was the highest since 1940. Most of this gain was due to an increased tonnage of zinc-lead ore produced from the Butte Hill mines and dumps of the Anaconda Copper Mining Co. and to a substantial rise in production from the Mike Horse mine, which was operated all of 1951 in contrast to 6 months' operation in 1950. Other large producers were the Jack Waite mine and the Blacktail property. Anaconda company-owned and leased operations accounted for 78 percent of the State lead in 1951. Of the total lead output 89 percent was recovered from zinc-lead ore and 7 percent from lead ore.

Arizona's output of lead in 1951 dropped 34 percent below the 1950 total owing chiefly to a marked decrease in the production of zinc-lead ore from the Copper Queen mine at Bisbee, where zinc-lead ore reserves were nearly depleted. The St. Anthony property at Tiger was the leading lead producer in the State during the year; it was followed by the Iron King mine at Humboldt, San Xavier mine near Sahuarita, Flux group near Patagonia, Copper Queen mine at Bisbee, and Aravaipa group near Klondike. About 92 percent of the State total lead was obtained from zinc-lead ore and 5 percent from lead ore.

Mine production of lead in California in 1951 decreased 12 percent from the record output established in 1950. The Anaconda Copper Mining Co. Inyo County properties, the Darwin group, Coso district, and the Shoshone group, Resting Springs district again furnished the bulk of the State lead. Moderate quantities of lead were recovered from ore from the Coronado Copper & Zinc Co. Afterthought mine and from flue dust accumulated at the site of the abandoned Kennett Copper smelter, both in Shasta County. About 58 percent of the total output was derived from lead ore and 35 percent from zinc-lead ore.

Digitized by Google

Lead output in Washington in 1951 decreased nearly 23 percent from the record quantity produced in 1950, chiefly because of reduced output at the Grandview and Bonanza mines. The 4 largest mines—Pend Oreille, Grandview, Bonanza, and Deep Creek—supplied 98 percent of the State total lead during the year. Over 77 percent of the output was from zinc-lead ore and most of the remainder from lead ore.

Nevada lead output dropped 24 percent in 1951 compared with 1950. Of the State total, 66 percent was mined in the Pioche district, Lincoln County. The leading producers in order of output were the Pioche group and Ely Valley mine, Pioche district; San Rafael mine, Quartz Mountain district; Copper Canyon mine, Battle Mountain district; and Bristol mine, Jack Rabbit district. About 77 percent of the total lead output was recovered from zinc-lead and zinc-lead-copper ores and most of the remainder from lead ore.

Production of lead in New Mexico increased 41 percent in 1951. Such a large percentage gain was to be expected as output in 1950 was unusually low, because most of the mines that shut down when metal prices declined in 1949 remained idle several months in 1950. The largest producers were the Ground Hog and Bayard groups in the Central district and the Lynchburg mine in the Magdalena district. Zinc and zinc-lead ore yielded 80 percent of the State total lead and lead ore 18 percent in 1951.

TABLE 2.—Mine production of recoverable lead in the United States, 1942–46 (average) and 1947–51, by States, in short tons

State	1942–46 (average)	1947	1948	1949	1950	1951

Digitized by Google

Mines in States east of the Mississippi River produced 6 percent less lead in 1951 than in 1950. Decreased output was attributed to a 54-percent drop in production from Virginia, where the Austinville mine of the New Jersey Zinc Co. was idle from April to October 1 because of a strike. Lead is produced chiefly as a byproduct or co-product of zinc and fluorspar mining in these States.

Small quantities of lead were also recovered in 1951 from ores mined in Alaska, Oregon, South Dakota, Texas, and Arkansas.

Digitized by Google

The 25 leading lead-producing mines in the United States in 1951, listed in table 4, yielded 68 percent of the total domestic output; the 10 leading mines produced 51 percent and the 4 leading mines 36 percent.

Detailed information on the production of mines and mining districts in the United States may be found in the chapters of this volume dealing with the mine production of gold, silver, copper, lead, and zinc in the various States.

SMELTER AND REFINERY PRODUCTION

Pig (refined) lead produced in the United States is derived from three principal sources—domestic mine production, imports of foreign ores and base bullion, and scrap materials (treated largely at secondary smelters)—and is recovered at primary refineries that treat ore, base bullion, and small quantities of scrap and at secondary plants that process scrap exclusively. Of the 13 primary lead plants in the United States, 6 combine smelting and refining operations, 5 produce only base bullion (containing approximately 98 percent lead plus gold and silver, and small quantities of other impurities recovered from the ores smelted), and 2 confine their activities to refining. Refined lead and antimonial or "hard" lead may be produced by both primary and secondary plants. Because of the large quantity of hard lead, such as battery scrap, melted at secondary smelters, the output from this type of operation is essentially antimonial lead. Statistics on the production of refined lead and alloys at secondary plants are given in the Secondary Lead section of this chapter.

Digitized by Google

Of the 13 primary smelters in operation in 1951, all but 2 consumed substantial quantities of primary materials in the form of ores and concentrates. During the year these 11 plants consumed 435,894 short tons (lead content) of this type of material, of which 18 percent was of foreign origin. In 1950, 511,433 tons (lead content) of ores and concentrates were consumed, 17 percent of which was foreign.

Active Lead Smelters and Refineries.—Primary lead smelters and refineries operating in the United States in 1951 were as follows:

California: Selby—Selby plant, American Smelting & Refining Co. (smelter and refinery).
Colorado: Leadville—Arkansas Valley plant, American Smelting & Refining Co. (smelter).
Idaho: Bradley—Bunker Hill Smelter, Bunker Hill & Sullivan Mining & Concentrating Co. (smelter and refinery).
Illinois: Alton—Federal plant, American Smelting & Refining Co. (smelter and refinery).
Indiana: East Chicago—U. S. S. Lead Refinery, Inc. (refinery).
Kansas: Galena—Galena plant, Eagle-Picher Co. (smelter and refinery).
Missouri: Herculaneum—Herculaneum plant, St. Joseph Lead Co. (smelter and refinery).
Montana: East Helena—East Helena plant, American Smelting & Refining Co. (smelter).
Nebraska: Omaha—Omaha plant, American Smelting & Refining Co. (refinery).
New Jersey: Barber—Perth Amboy plant, American Smelting & Refining Co. (smelter and refinery).
Texas: El Paso—El Paso plant, American Smelting & Refining Co. (smelter).
Utah:
Midvale—Midvale plant, United States Smelting, Refining & Mining Co. (smelter).
Tooele—Tooele plant, International Smelting & Refining Co. (smelter).

REFINED LEAD

Primary refineries in the United States produced 422,000 short tons of refined lead in 1951 or 18 percent less than the 1950 output of 514,000 tons.

Of the 418,000 of refined lead produced from primary sources during the year, domestic ores and base bullion were the source of 82 percent and imported ores and base bullion of 18 percent, the same proportions for domestic and foreign materials as in 1950. Table 7 gives the production of refined lead by source material and country of origin. Details of the sources of lead from domestic ores are given in the Mine Production section of this chapter.

TABLE 6.—Refined lead produced at primary refineries in the United States, 1947–51, by source material, in short tons

ANTIMONIAL LEAD

Antimonial lead output at primary refineries in 1951 rose 14 percent above the 1950 level but was well below the record high established in 1948. Production increased at 3 of the 5 primary plants producing the alloy. Distribution of antimonial lead production at primary refineries in 1947–51 by source material is shown in table 8, as is also the average antimony content.

Although antimonial lead is an important byproduct of the refining of base bullion, the quantity derived from this source is only a small part of total domestic output. The major production is recovered from the smelting of antimonial lead scrap at secondary smelters. Production data from lead-smelting plants treating scrap materials exclusively are summarized in the following section.

TABLE 8.—Antimonial lead produced at primary lead refineries in the United States, 1947–51

Year	Production (short tons)	Antimony content		Lead content by difference (short tons)			
		Short tons	Percent	From domestic ore	From foreign ore	From scrap	Total
1947	86,075	4,933	5.7	14,836	9,850	56,456	81,142
1948	100,764	5,760	5.7	29,561	15,918	49,525	95,004
1949	41,402	3,385	8.2	692	4,620	32,705	38,017
1950	57,959	4,504	7.8	10,728	4,344	38,383	53,455
1951	65,309	4,416	6.7	17,372	9,218	34,303	60,893

SECONDARY LEAD

Some scrap lead is treated at primary smelters, but the greater part is processed at a large number of plants that specialize in the treatment of secondary materials. Secondary lead is recovered in the form of refined lead, antimonial lead, and other alloys.

Digitized by Google

Secondary lead recovery in 1951 was the highest on record—7 percent above the 1950 figure—and exceeded the domestic mine output of recoverable lead for the sixth consecutive year. Data on recovery, by type of plant, in 1947-51 are shown in table 9. Detailed information on secondary lead appears in the Secondary Metals—Nonferrous chapter of this volume.

TABLE 9.—Secondary lead recovered in the United States, 1947–51, in short tons

Grand total:					
Short tons	511,970	500,071	412,183	482,275	518,110
Value	$146,423,420	$179,025,418	$130,249,828	$130,214,250	$179,266,060

LEAD PIGMENTS

The principal lead pigments are litharge, white lead, red lead, sublimed lead, leaded zinc oxide, and orange mineral. These products are manufactured for the most part from metal, but some ore and concentrates are converted directly into pigments. Details of the production of lead pigments are given in the Lead and Zinc Pigments and Zinc Salts chapter of this volume.

CONSUMPTION AND USES

Domestic lead consumption (including lead in lead ore consumed directly in the manufacture of lead pigments and salts) totaled 1,184,793 short tons in 1951. Of the total consumed, 749,590 tons was refined soft lead and 296,555 tons was contained in antimonial lead, 26,205 tons in unmelted white scrap, 45,784 tons in "percentage metals" (the alloy pig metals derived from the secondary lead industry), 24,303 tons in copper-base scrap, 29,538 tons in drosses and residues, and 12,818 tons recovered from ores in leaded zinc oxide. In 1951, 42 percent of all lead consumed was used in the manufacture of metal products (excluding storage batteries). Production of the 3 largest lead-consuming items—batteries, cable coverings, and tetraethyl fluid—took 54 percent of all lead consumed during the year. Batteries took 32 percent and cable covering and tetraethyl fluid each 11 percent.

STOCKS

Producers' Stocks.—Lead stocks, as reported by the American Bureau of Metal Statistics, are shown in table 13. Stocks of refined and antimonial lead include metal held by all primary refiners and by some of the refiners of secondary metal who produce soft lead. According to reports released by the American Bureau of Metal Statistics, monthly stocks of refined lead and antimonial lead in 1951 were, on the average, less than half of the tonnage held in comparable periods of 1950. Inventories totaled 25,339 tons on December 31, 1951, compared with year-end stocks of 35,619 tons in 1950.

TABLE 13.—Stocks of lead at smelters and refineries in the United States at end of year, 1947–51, in short tons

[American Bureau of Metal Statistics]

	1947	1948	1949	1950	1951
Refined pig lead	13,634	29,050	61,329	28,894	18,518
Antimonial lead	7,694	9,594	9,095	6,725	6,821
Total	21,328	38,644	70,424	35,619	25,339
Lead in base bullion—					
At smelters and refineries	7,652	9,697	16,364	11,993	11,315
In transit to refineries	5,447	4,101	3,696	4,959	3,909
In process at refineries	16,328	17,939	15,561	15,341	15,700
Total	29,427	31,737	35,621	32,293	30,924
Lead in ore and matte and in process at smelters	77,199	76,373	95,481	69,757	67,817
Grand total	127,954	146,754	201,526	137,669	124,080

The Bureau of Mines annual survey of primary smelters and refiners indicated stocks of 28,894 tons (lead content) of refined soft lead at plants on January 1, 1951, and 18,517 tons on December 31, 1951. Primary antimonial lead stocks at these same plants totaled 6,152 tons (lead content) at the beginning of 1951 and 6,367 tons at the end of the year. In terms of lead content, stocks of ore and concentrates at the operating primary smelters and refineries increased from 42,346 tons to 44,378 during the same period. The inventory of base bullion at refineries that receive base bullion as a raw material and at smelters that produce base bullion for shipment to refineries was 11,658 tons at the beginning of the year and 12,731 tons on December 31, 1951. Stocks of in-process base bullion or work lead at four combination smelter-refinery plants are not included in reports to the Bureau of Mines. No direct comparison can be made between these data and the figures of the American Bureau of Metal Statistics. Figures reported to the Bureau of Mines represent physical inventory at the plants, irrespective of ownership, and do not include material in process or in transit.

Consumers' Stocks.—Consumers' stocks of lead decreased 27 percent during 1951. The decline was consistent through the first 6 months, was reversed in July, and then continued the downward trend through the remainder of the year, dropping from 139,884 tons on January 1 to 102,760 on December 31. Stocks of antimonial lead gained 2 percent and percentage metals 9 percent, but stocks of refined soft lead dropped 35 percent, white-metal scrap 42 percent, copper-base scrap 8 percent, and drosses 46 percent.

TABLE 14.—Consumers' stocks of lead in the United States at end of year, 1948–51, by type of material, in short tons, lead content

Year	Refined soft lead	Antimonial lead	Unmelted white scrap	Percentage metals	Copper-base scrap	Drosses, residues, etc.	Total
1948	62,077	35,088	4,828	7,932	2,301	6,972	119,198
1949	64,542	16,837	2,957	5,405	2,087	5,439	97,267
1950 [1]	87,285	27,737	5,406	6,446	1,558	11,452	139,884
1951	56,731	28,221	3,140	7,054	1,429	6,185	102,760

[1] Revised figures.

PRICES

The two major markets for lead in the United States are New York and St. Louis. Much of the lead produced domestically is sold at prices normally based upon quotations in these markets. Since suspension of trading on the London Metal Exchange in September 1939 the London market has had no direct influence on New York quotations, and the differential between St. Louis and New York prices has remained 0.2 cent a pound, an amount approximating the freight charges between the two cities.

The price of lead was controlled by the Office of Price Stabilization during 1951. Ceiling prices were established for lead on January 26, 1951, at the highest price (for each seller) at which sales were made between December 19, 1950, and January 25, 1951. Thus a number of ceiling prices were established. The bulk of lead sales, however, were at 17.00 cents per pound, common lead, New York. The 17.00-cent price remained in effect until October 2, when the Office of Price Stabilization permitted a rise of 2 cents a pound. No further change in price occurred in 1951.

TABLE 15.—Average monthly and yearly quoted prices of lead at St Louis, New York, and London, 1949–51, in cents per pound [1]

The official London price of £136 per long ton of lead (equivalent to 17.00 cents per pound computed on the 280.00-cent per pound base), fixed by the Ministry of Supply on November 1, 1950, remained in effect until April 1, 1951, when the Ministry raised the price to £160 (20.00 cents). The price was increased again on July 14 to £180 (22.50 cents). On October 1 the official price was reduced to £175 (21.88 cents), at which level it remained for the balance of the year. (During the latter half of 1951 sterling exchange rates varied between 278.63 and 280.00 cents per pound, hence actual dollar prices were at times slightly less than the 21.88-cent equivalent shown).

FOREIGN TRADE [2]

Tariff.—There has been a tariff on lead for well over a century, ranging from a low of 15 percent ad valorem to a high of 3 cents a pound. The import duty set by the Tariff Act of 1930 on lead-bearing ores, flue dust, and mattes (lead content) was 1½ cents per pound and on lead bullion, pigs, bars, scrap lead, antimonial lead, type metal, babbitt metal, solder, and alloys not specifically provided for, 2⅛ cents per pound. In accordance with the Mexican Trade Agreement of January 30, 1943, these rates were reduced to ¾ cent and 1$\frac{1}{16}$ cents per pound, respectively. In June 1948 these duties were suspended for 1 year by act of Congress. As the Congress took no action on a bill to extend the suspension beyond June 30, 1949, the expiration date of the original legislation, the import duties provided for in the Mexican Trade Agreement were reinstated automatically on July 1, 1949, and continued at those levels throughout 1950. Abrogation of the agreement, effective January 1, 1951, restored the full duties established by the Tariff Act of 1930. The Mexican Agreement was reaffirmed on June 6, 1951, reestablishing the 1$\frac{1}{16}$-cent and ¾-cent duties on pig lead and lead in ores and concentrates, respectively.

Imports.—Total imports of lead declined to 258,000 tons in 1951 or less than half the record quantity of 542,000 tons imported in 1950. The drastic decline resulted from the reluctance of foreign producers to export lead to the United States, when the Free World market price for lead was considerably higher than the United States ceiling price. However, since foreign demand could not absorb the available foreign lead, stocks in the hands of producers accumulated until producers were compelled to reduce prices. By the end of the year Free World prices were essentially at the United States level.

Of total imports, 178,900 tons (69 percent) was as pigs and bars, 67,700 tons (26 percent) in ore and matte, 9,100 tons (4 percent) as reclaimed, scrap, etc., and 2,300 tons (1 percent) in base bullion. Canada supplied 32 percent of the pigs and bars, Mexico 21 percent, Yugoslavia 20 percent, Peru 18 percent, Australia 8 percent, and other countries 1 percent. Imports of ore and matte came principally from Peru, Bolivia, Africa, Canada, and Australia.

[2] Figures on imports and exports compiled by M. B. Price and E. D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

[2] Less than 0.5 ton.

WORLD REVIEW

Lead is produced in many countries, but four—United States, Mexico, Australia, and Canada—have accounted for about three-fifths of the world output in recent years, as is apparent from tables 20 and 21, which show world mine and smelter production by countries 1945–51, insofar as statistics are available.

Algeria.—*See* French Morocco.

Argentina.—The chief lead-producing district in Argentina is the Aguilar, where the Compania Minera Aguilar, S. A., a subsidiary of the St. Joseph Lead Co., operates the Aguilar group of mines. Production in 1951 was 70 percent of the mill capacity, because of exchange difficulties which made it difficult to get adequate supplies and equipment. During the year, 199,904 metric tons of ore was milled, from which 26,219 tons of lead concentrate was produced. This represents an increase over the previous year, when 174,398 tons was milled to produce 23,777 metric tons of concentrate. The lead con-

Digitized by Google

centrate was smelted at the National Lead Co., S. A., smelter at Barranqueras, Chaco Territory.

Australia.—Both mine and smelter output of lead increased slightly above the 1950 level despite continued shortages of labor and supplies and the requirement that producers supply domestic needs at a price approximately one-third of that received for export lead. Mine output in 1951 was 228,000 metric tons or approximately 14 percent of the world total.

The most important districts are Broken Hill, New South Wales, and Mount Isa, Queensland. Other large deposits occur at Captain's Flat (Lake George Mines) New South Wales and the Read-Roseberry mine in Tasmania.

[1] Data derived in part from Monthly Bulletin of the United Nations, Statistical Summary of the Mineral Industry (Imperial Institute, London), and the Yearbook of the American Bureau of Metal Statistics.
[2] Revised figure.
[3] Includes scrap.
[4] Data not yet available; estimate by senior author of chapter included in total.
[5] Estimate.
[6] American and British zones only.
[7] Figures cover lead refined from domestic and foreign ores; refined lead produced from foreign base bullion not included.

Four companies—the North Broken Hill, Ltd., the Broken Hill South, Ltd., the New Broken Hill Consolidated, Ltd., and the Consolidated Zinc Corp., Ltd.—mine and mill the Broken Hill ores. During 1951 the Consolidated Zinc Corp., Ltd., continued its program of developing and equipping its mine for increased output. In the course of the year the company mined and milled 440,302 tons of ore containing 58,981 tons of recoverable lead. In addition, it hoisted and milled 211,608 tons of ore (16,706 tons recoverable lead content) for the account of New Broken Hill Consolidated, Ltd. The latter company made excellent progress during the year with development of the No. 19 level and construction of new mine shafts, concentrator, and power plant, which were expected to be placed in service in late 1952. Broken Hill South, Ltd., reported mining 279,319 long tons of ore which assayed 12.0 percent lead, 12.1 percent zinc, and 7.8 ounces of silver per ton. The tonnage mined by North Broken Hill, Ltd., increased slightly, but recoveries of both lead and zinc declined because

Digitized by Google

the ores treated from the British, Junction, and Block 14 areas were partly oxidized.

The Electrolytic Zinc Co. of Australasia operated the Hercules and Roseberry mines in the Read-Roseberry district of Tasmania, increasing both reserves and output of lead during the year. Output of ore for the year ended June 30, 1951, was 159,429 long tons, which yielded 10,084 long tons of lead concentrate, 46,153 of zinc concentrate, and 3,781 of copper concentrate.

Mount Isa Mines, Ltd., which owns and operates the great Mount Isa deposits in Queensland, continued its operations at a normal rate. During the year the company became interested in working the Protheroe lead mine at Northampton, Western Australia, which produced about 500 tons of lead concentrate monthly.

Bolivia.—In 1951 Bolivia exported 30,000 metric tons of recoverable lead in ore. Small miners continued to dominate the lead industry and provided 63 percent of the total lead exported, with the Aramayo and Hochschild groups furnishing 15 percent each. Although official figures were not available on the amount of lead smelted in Bolivia, it was known that the 3 smelters at La Paz, Cochabamba, and Tupiza had a bullion capacity of about 500 tons per month. A fourth smelter under construction at Oruru was expected to increase total capacity to an estimated 700 tons of bullion per month.

Canada.—Although the value of recoverable lead from Canadian mines was 17 percent greater than in 1950, the output (143,000 metric tons) was the least since 1933. The Sullivan mine of the Consolidated Mining & Smelting Co., Kimberley, British Columbia, continued to be the principal source of Canadian lead. Ore production in 1951 at this mine totaled 2,533,212 short tons compared to 2,680,962 tons in 1950. As in 1950 the grade decreased somewhat because of the mining of lower grade ores and the dilution consequent to mining pillars. The company milled about 10,000 tons of ore daily, using a combination of sink-float and flotation equipment. The waste from the sink-float plant, which amounted to about 25 percent of the feed, was used for backfill in the mine. Lead concentrate was treated at the company smelter, Trail, B. C., with ores and concentrate from other properties. Production of refined pig lead at the Trail plant totaled 162,712 tons in 1951 compared with 170,364 in 1950. Work progressed on construction of new lead-smelting facilities that would both improve metallurgical efficiency and increase capacity. Accumulated and current lead-bearing residues from the Trail zinc smelter were to be smelted.

The Big Bull and Tulsequah Chief mines in northwest British Columbia came into production during the year, jointly producing 250 tons of complex ore per day. The Yale Lead and Zinc Mine, 30 miles northeast of Nelson, B. C., began producing at the rate of 190 tons of ore daily in April. Other mines were being developed in British Columbia and Nova Scotia, and exploration of the Pine Point mine on the south shore of Great Slave Lake was continued.

French Morocco and Algeria.—Perhaps the outstanding development in the lead industry abroad in 1951 was the increased production of the mines of French Morocco. Mine output of 68,100 metric tons of lead was 40 percent above that of 1950. It was unofficially reported that Société des Mines Zellidja milled 835,889 tons of ore to recover

Digitized by Google

38,885 tons of 74-percent lead concentrate and 29,820 tons of 54-percent zinc concentrate. The company No. 2 mill had a daily ore-treatment capacity of 3,300; it was scheduled to treat all Zellidja ore after August 1, 1952. Total Zellidja reserves were estimated to be 27,000,000 tons, of which 10,000,000 tons may be marginal. Other important producers of lead in French Morocco were the Société des Mines d'Aouli and the Compagnie Royale Astusienne des Mines.

The lead-zinc district extends into adjacent Algeria, where the Société Nord Africaine du Plomb was developing an ore deposit containing 16 percent zinc and 2 percent lead. The operations were directed from Zellidja, and plans provided for milling 600 tons of ore daily at Zellidja's No. 1 mill beginning about August 1952.

The lead smelter of the Société des Mines de Zellidja at Qued-el-Heimer produced 18,400 tons of refined lead in 1951. Capacity of the smelter was said to be 4,000 tons of concentrate monthly.

Guatemala.—Output of the Caquipec mine in the Department of Alta Verapaz more than tripled that of 1950 and would have been greater except for transportation difficulties. The lead ores, which ranged from 20 to 42 percent lead, were shipped to the United States and Canada for smelting. Small producers in the Department of Huehuetenango continued to mine and smelt pig lead for the domestic market by primitive methods.

Mexico.—Mine production of lead declined somewhat in 1951 as higher prices permitted lower grade ores to be profitably treated. According to the annual report to the stockholders of the San Francisco Mines of Mexico, Ltd., shortage of electrical power forced some curtailment of production. The company milled 597,400 metric tons of ore compared to 623,000 tons in 1950 and produced 45,756 tons of 64.34-percent lead concentrate, 68,452 tons of 55.18-percent zinc concentrate, and 6,148 tons of 26.24-percent copper concentrate. Ore reserves at the end of September 1951 were 4,208,000 tons, containing 6.50 percent lead, 9.35 percent zinc, and 0.65 percent copper.

South-West Africa.—The Tsumeb Corp., Ltd. operated the very rich and important Tsumeb mine near the north boundary of the territory. In spite of transportation difficulties with the narrow-gage railway between Tsumeb and Vsajos, progress continued in expansion of facilities and production. In the year ended June 30, 1951, the concentrator treated 392,780 short tons of ore, from which 32,637 tons of lead, 11,231 tons of copper, and 12,847 tons of zinc were recovered. Sinking of the new vertical 7-compartment De Wet shaft progressed to a depth of 2,460 feet by the end of 1951. The shaft was to be sunk to 4,150 feet and equipped with a hoist and skips capable of handling 2,000 tons of ore daily. During the year the Tsumeb Corp. investigated a lead-zinc deposit near Windhoek. The South-West Africa Co. expanded milling capacity at the Abenab-West lead-vanadium property near Grootfontein.

Tunisia.—During 1951, 12 mines in Tunisia produced 33,915 tons of lead concentrate containing 21,250 metric tons of lead. In the same period the Megrine, Djebel Hallouf, and Bizerte lead smelters smelted 39,350 tons of ore and concentrate to produce 22,906 metric tons of pig lead.

Lead and Zinc Pigments and Zinc Salts

By Robert L. Mentch

GENERAL SUMMARY

MODERATE declines in shipments of lead and zinc pigments and zinc salts featured the industry in 1951. However, owing largely to continuing defense activities, shipments remained substantially above those of 1949. Decreases from 1950 to 1951 in shipments of zinc pigments ranged from 3 percent for lithopone to 31 percent for leaded zinc oxide. Litharge and white lead (dry and in oil) declined 13 and 22 percent, respectively, while red-lead shipments were approximately the same as in 1950. Zinc salts (zinc sulfate and zinc chloride) decreased 2 and 6 percent, respectively.

Decreases in shipments of pigments and salts are attributed partly to decreases in the volume of business in industries that are important consumers of these products: Passenger-automobile production dropped 20 percent in 1951 (truck output rose 7 percent), and consumption of natural and synthetic rubber declined 3 percent (natural rubber fell 37 percent and synthetic rubber increased 41 percent) compared with 1950. The value of sales of varnish and lacquer materials was 5 percent greater than in 1950, the value of public construction increased 27 percent, and the value of private construction was approximately the same as in 1950; paint and construction gains, however, in part reflected rising costs of materials and labor.

Supplies of lead and zinc, the chief raw materials of the pigments industry, were smaller in 1951 than in 1950; yet the demand for these as metal continued high, causing a reduction in quantities available for the manufacture of pigments and also partly accounting for the decreases in shipments. Ceiling prices were established for lead and zinc on January 26, 1951, at the highest price (for each seller) at which sales were made between December 19, 1950, and January 25, 1951. Thus a number of ceiling prices were maintained for both lead and zinc. The bulk of lead and zinc sales, however, was at 17 cents per pound and 17.50 cents, respectively. These prices were for common lead, New York, and Prime Western grade slab zinc, East St. Louis, and remained in effect until October 2, 1951, when the Office of Price Stabilization permitted rises of 2 cents per pound for both metals.

Lead- and zinc-pigment price quotations maintained their historically close relationship to pig-lead and slab-zinc prices throughout the year. There were virtually no fluctuations, owing to imposition of ceiling prices by the Office of Price Stabilization early in the year. Quotations advanced up to 2 cents a pound shortly after the 2-cent rise in lead- and zinc-metal prices in October. Zinc-pigment prices reached alltime highs during the year. Lead-pigment prices, although relatively high, did not attain the record levels of 1948 and early 1949.
